## SAFE PRACTICES IN THE INDUSTRIAL USE OF CARBON TETRACHLORIDE

HENRY FIELD SMYTH, M.D.

AND

HENRY F. SMYTH JR., PH.D.

PHILADELPHIA

Carbon tetrachloride, being the cheapest noninflammable solvent obtainable, has been in use in increasing amounts for over thirty years as a fire extinguisher, as a dry cleaning agent and for degreasing, fat extraction and similar purposes, as well as in medicine, more or less, as an anthelmintic and a cleansing agent in dermatology. From time to time reports have appeared in the literature on nonfatal and at times fatal poisonings from its careless use.<sup>1</sup> These reports and experimental work have indicated however that, if properly used in industry in closed processes, or with adequate exhaust ventilation in open processes, or in limited amounts in the open air, no harm will result.

The acute toxicity of its vapors is fairly well understood and Lehmann<sup>2</sup> gives 1,600 volumes of vapor per million volumes of air (parts per million) as safe for short exposures, although we feel that this is safe for only ten to thirty minutes. McCord,<sup>3</sup> on the basis of a comparatively brief exposure of rabbits, concludes that the safe limit for continuing exposures is somewhat below 500 parts per million; but, since Lehmann<sup>2</sup> has stated that rabbits are particularly susceptible to vapors of this type, because of a tendency to develop toxic pneumonia, this figure must be accepted as tentative. Davis,<sup>4</sup> as the result of a limited number of tests with human beings, concludes that more than 100 parts per million may be hazardous but that single exposures to small concentrations do not produce lasting injury. No other published work attempts definitely to fix a safe concentration for continuous exposure, and the reports quoted are not based on sufficient subjects or on long enough intervals to assure their adequacy, although they do indicate that low concentrations are reasonably safe.

The present work was undertaken in an effort to fill some of the gaps in previous work, to establish definitely safe concentrations for continuous exposure, to determine if possible what clinical signs might be taken

as evidence of early toxic action, and to determine to what concentrations workers are being exposed, correlating the concentrations with physical examinations when possible. Details of methods and results cannot be given in the space of the present paper but are all a matter of record elsewhere.<sup>5</sup>

### ANIMAL EXPERIMENT

A total of 333 animals was used, together with their offspring during the year of study, and included guinea-pigs, white rats and monkeys. About half of the pigs were fed 1.2 Gm. of calcium lactate a day in addition to their regular diet to determine protective action. Animals were exposed eight hours a day five days a week for ten and one-half months (225 exposures were made in all) to controlled, accurately measured concentrations of pure carbon tetrachloride vapors in concentrations of 25, 50, 100, 200 and 400 parts per million. It is of interest to know that the usual commercial grades are almost pure, containing only about 0.2 per cent of foreign matter, chiefly carbon disulfide, far too little to affect vapor toxicity. Studies of micro-pathologic changes of the liver, kidney, spleen, adrenal, heart, sciatic and optic nerve, and ocular muscle were made.

The guinea-pigs were quite susceptible to the vapors, many dying, in line with Lehmann's<sup>2</sup> statement as to the sensitivity of the very similar rabbits. No monkeys died, and only two rats, the latter after more than 100 exposures to 400 parts per million. No effect on alertness and general good health was seen. No abnormalities were found in blood counts, although active red cell destruction took place in the spleen. No effect on urine chemistry was seen, but many rats showed high icteric indexes, van den Bergh tests and low blood calciums, although these developed irregularly after definite liver changes were seen. Monkey blood chemistry was normal. The rats exposed to 50 parts per million grew more rapidly than did the controls, those exposed to 100 parts per million equaled the controls and those exposed to 200 and 400 parts per million grew a little slower. The rats exposed to 50 parts per million were 40 per cent more fertile than the controls, those exposed to 100 parts per million equaled the controls, and those exposed to 200 and 400 parts per million were less fertile. The addition of calcium to the diet of guinea-pigs increased resistance to the vapors but did not increase blood calcium.

Typical cirrhosis of the liver was produced in guinea-pigs that survived long enough to reach this stage as well as in rats, but no monkey was sufficiently injured. A surprisingly great degree of regeneration in both liver and kidney originally damaged by exposure took

place while exposures continued, and within four to eight weeks after exposures were stopped almost all animals had normal livers save for contracted bands of connective tissue, and kidneys also appeared normal. After this rest period the tissues of even monkeys exposed to 225 days at 200 parts per million (the highest concentration monkeys received) were com-

TABLE 1.—Summary of Carbon Tetrachloride Vapor Concentrations Found in Industry

pletely normal on microscopic examination. Definite adrenal damage was seen in guinea-pigs but not in rats or monkeys. Acting on the suggestion of MacNider's<sup>6</sup> paper on the increased resistance of liver cells regenerated after injury produced by uranium, a few comparisons were made of the resistance to toxic effect from short anesthetizing exposures (thirty minutes to 20,000 parts per million = 2 per cent) after rats had been allowed to recover for from one to two months following six

As a result of these experiments, on the assumption that, of the animals used, monkeys resemble human beings most closely and rats next most closely, it is believed that 100 parts per million is a safe concentration for continuous exposure to carbon tetrachloride vapors. It is believed that exposures of small omnivorous animals to vapors eight hours a day from early adolescence to decline of fertility, as was done here, is equivalent to many years of exposure of adult human beings in toxic action, owing to physiologic action during tissue growth. Pups of rats exposed to 50 parts per million were exposed from birth and were no more affected than were their parents, nor were any pups more affected than were their parents.

VAPOR CONCENTRATIONS FOUND IN INDUSTRY

For measurement of concentrations of carbon tetrachloride vapor in establishments manufacturing the solvent and using it, a 50 cm. portable Zeiss interference refractometer (or interferometer) was used. Samples of air were taken from a point near the worker's nose at intervals of from ten seconds to five minutes, spaced to give a reliable average of working conditions and to catch any peaks of concentration created by the job. Tests were made throughout the five plants manufacturing the solvent in this country, in the plants of twenty-three dry cleaning establishments using five different makes of machine, and in eight plants repack- ing the solvent or using it in chemical processes. The dry cleaning establishments visited were all well cared for installations, so they actually represented the best conditions rather than the average conditions of the industry. A total of 2,000 measurements was made, the results being summarized in table 1. Because of condensation of data, the table does not give the true average exposure of the workmen during their eight hour day, giving only the average for the process. When the usual time a man works at a given job is considered, only two of the plants visited provided jobs in which average concentrations were above 100 parts per million, which the animal work indicated to be a safe concentration. It is our experience that

months or more of exposure to low concentrations. Definite marked injury was produced in the livers and kidneys of previously unexposed rats but only slight injury or no injury at all in these organs of animals previously exposed to concentrations of from 50 to 400 parts per million. As far as one can argue from this limited experiment, involving only thirteen rats, it seems that recovery from previous exposure endows the animals with more than normal resistance to injury from carbon tetrachloride.

high concentrations of this and other volatile materials in work places are usually due to overlooked leaks or to ignorance of the need of care rather than to inherent properties of the solvents.

PHYSICAL EXAMINATIONS

Physical examinations were made of ninety-six work- ers exposed to carbon tetrachloride vapors at their jobs; in most cases determinations were made at the particular point of work of these men. It is significant of the care being taken in the industry today that the highest average daily exposures found were 117 and 111 parts per million. The only peak concentrations

6. MacNider, W. deB.: The Resistance of Fixed Tissue Cells to the Toxic Action of Certain Chemical Substances, Science 81: 601-605 (June 21) 1935.

found to exceed 1,000 parts per million in places where men who were examined worked were 1,680 and 1,252 parts per million, but several men worked with air helmets in which peaks were over 1,000 parts per million. These peaks invariably lasted only one-half minute or thereabouts.

Wirtschafter<sup>7</sup> reported concentric restriction of visual fields as probably being significant of carbon tetrachloride injury. We fully realize that a number of factors make our measurements of visual fields uncertain, because of the conditions of work necessary in factories and because of the use of a portable perimeter only. The measurements therefore must be regarded as approximate and subject to correction if repeated in an ophthalmologist's office. Dr. Burton Chance, Philadelphia ophthalmologist, aided in interpreting the fields obtained. These were considered definitely restricted and possibly significant of carbon tetrachloride injury in the present study when the restriction toward the bottom and outer edge was 30 degrees or more.

Although it is realized that continuing toxic exposure may produce anemia, and examination of animal spleens indicated active red blood cell destruction, no worker was found with this condition. Following Boerner,<sup>8</sup> 6,000 lymphocytes per cubic millimeter and 600 monocytes were considered normal maximums. Minot and Smith's<sup>9</sup> studies with perchlorethane governed the addition of 10 per cent monocytes as a maximum, so that if either the percentage or the absolute number exceeded one of these figures it was considered abnormal. Icteric indexes of 8, and indirect van den Bergh reactions of 0.2 per hundred cubic centimeters are considered normal maximums, and blood calcium of 7 mg. per hundred cubic centimeters is considered a normal minimum. Blood sugar was not determined in order to avoid making too great a demand on the workers. A total of 35 Gm. of nitrogen in a twenty-four hour specimen of urine and 2.25 Gm. of total sulfate were taken as normal maximums. Takahashi<sup>10</sup> reported both values raised in injury caused by carbon tetrachloride. Bilirubin or albumin was not found in any urines.

For susceptible workers, length of exposure may be important, but nineteen workers were examined each of whom had worked at least ten years with carbon tetrachloride and one of them twenty-five years, none with any evidence of severe injury. Eleven of the nineteen showed no departures from normal at all, five showed only one minor departure each among the eight tests already mentioned, and three showed two minor departures each.

While one might usually anticipate rather definite correlation between degree or duration of exposure and evidence of injury, personal susceptibility not infrequently varies greatly, as do contributing factors such as habits, diet and the use of stimulants, so that correlations may not be found. Low calcium and low carbohydrate diets, especially, increase toxic action of carbon tetrachloride, as does the excessive use of alcohol.

Table 2 summarizes the physical examinations, giving the number of times one of the eight selected clinical studies fell outside the normal range. No worker was found to be seriously affected by the exposure to vapor. Among eight men working in concentrations averaging more than 100 parts per million, four showed no abnormal changes, two had restricted visual fields, and one had low calcium and one high urinary nitrogen. Among seventy-three working in concentrations averaging under 100 parts per million, thirty-eight gave no deviations from normal, eighteen high icteric indexes, twelve low blood calciums, five high van den Bergh reactions, seven restricted visual fields, and thirteen high lymphocytes or monocytes. A similar distribution was found among ten men working in unmeasured concentrations. None of the deviations from normal were marked. No man departed from normal in more than three out of the eight tests studied. Limitation of space prevents a more detailed presentation here.

Fig. 1.—Liver of rat 377, showing advanced cirrhosis, color yellow; 119 exposures to 400 parts per million.

Men with histories of long exposure to carbon tetrachloride undoubtedly had developed resistance just as did experimental animals and actually showed fewer abnormalities than did men just starting work. No man considered materially or appreciably weakened by exposure was found, no pallor or jaundice, and only one large liver, in a man admitting that he was chronically addicted to alcohol. He has now been given another job in which there is no carbon tetrachloride exposure. The men uniformly reported that subjective symptoms (headache, nausea, dizziness, undue fatigue and the like) suggestive of toxic action were present only during brief periods of bad ventilation, machine cleaning, spills, or other intermittent high exposures.

Since it is impossible to state that any of the abnormalities are actually due to carbon tetrachloride, and since it is certain that past exposures of most of the men exceeded the measured present exposure, the data can give evidence only of the fact that none of the men were markedly affected by exposure. The data therefore cannot be used alone in fixing on a safe concentration, but, considered together with the animal results, it is believed that a valid answer is possible.

However, the table does give information as to the abnormal clinical data to be expected from men continuously exposed to low concentrations of carbon tetrachloride without being markedly affected. From this standpoint the four tests that would apparently give the most information about the condition of exposed workmen and would presumably detect injury at the earliest possible date by an increase between successive examinations would be the icteric index, blood calcium, van den Bergh reaction and visual field. Any progressive change in the values for these tests among men regularly examined should be regarded with suspicion.

#### CARE OF EXPOSED WORKMEN

The suggestions given by Davis<sup>4</sup> for selection of workers for carbon tetrachloride exposure are considered excellent. Animal work indicates that the addition of available calcium to the diet is of value in prophylaxis, and probably also in treatment.

It is desirable that physical examinations of exposed workers be carried out at least twice a year. These should include determination of the icteric index, blood calcium, van den Bergh reaction and visual field mapping, as well as an examination of the general health. Preferably they should include also white cell and differential counts.

The development of an abnormal value in one of the single tests mentioned should call for watchfulness and an early reexamination, preferably one month after the first. If two abnormal values should develop, the exposure should be lessened and the man should be examined again in a month. If three are found, the

Fig. 2.—Liver of rat 395, showing regenerated cirrhosis, color normal; sixty-eight exposures to 400 parts per million, and 156 days without exposure; section resembles figure 3.

man should be moved to a department without carbon tetrachloride vapors. If at the end of a month in the new job his condition has returned to normal, his exposure may be resumed under a watchful eye. He may be found to be especially susceptible, in which case he should be given a permanent job without exposure to carbon tetrachloride. On the other hand, it is more likely that he will have developed an increased toler-

ance, the free period having sufficed for the development of regenerated, more resistant, parenchymatous cells.

#### COMMENT AND CONCLUSIONS

On the basis of animal experiments and on the assumption that monkeys resemble human beings most closely of the animals used and rats next most closely, it is concluded that 100 parts per million of carbon tetrachloride is a safe working concentration for con-

Fig. 3.—Liver of rat 393, showing regeneration from cirrhosis, with contracted septums; magnification 250. Seventy-six exposures to 400 parts per million. Sixty-three days without exposure.

tinuous exposure of workmen during the working day. Intermittent exposures averaging 100 parts per million when the duration of exposure is taken into account also are safe, and concentrations considerably higher than 100 parts per million are safe for short periods. It is believed that 1,000 parts per million is a safe peak concentration for half an hour a day, with an average of 100 parts per million during the rest of the day. These limits refer to day after day exposure in industry.

One hundred parts per million of carbon tetrachloride is noticed by most people coming into the atmosphere from one free from carbon tetrachloride as a barely perceptible characteristic odor, and particularly sensitive noses will detect 50 parts per million. If the average nose recognizes more than a faint odor on entering the workroom, an increase in ventilation is called for.

This concentration of 100 parts per million agrees with the conclusions of Davis<sup>4</sup> and is in general agreement with McCord,<sup>3</sup> who considered on the basis of short exposures that the safe concentration lay below 500 parts per million.

An animal continuously exposed to small amounts of carbon tetrachloride soon regenerates originally damaged liver cells and somewhat later regenerates damaged kidney cells, the regenerated or entirely new cells being more resistant to the vapors than were the original cells. It is concluded from this that in most cases men continuously exposed to small concentrations of carbon tetrachloride increase their resistance rather than increasing their susceptibility. This contrasts strongly with the action of benzene, the safe con-

centration of which is also set at 100 parts per million, since with that solvent injury may be progressive even after exposure is stopped.

It is entirely possible and practical to use carbon tetrachloride for almost any purpose without exceeding a concentration of 100 parts per million. Standard dry cleaning machinery already on the market will keep the concentration much below this figure and can be maintained in condition without anything more than ordinary care. Other processes using carbon tetrachloride can be operated in a similarly safe manner if plant managers realize that it is necessary, without unduly increasing expense and in some cases with a saving of solvent.

Of the total of ninety-six men exposed to carbon tetrachloride in industry, tests showed no one who could be considered seriously or even unmistakably injured by the solvent vapors. Nineteen of these men had worked more than ten years with the solvent, one of them twenty-five years. Although no unmistakable clinical test has been found to determine whether or not a given worker is being injured by carbon tetrachloride before the injury has progressed, it is believed that the series of tests which are suggested will establish strong probabilities, and for this reason a program of physical examinations of exposed workmen is suggested. The following of this program would protect men from more than the first stages of carbon tetrachloride injury, and men detected in these first stages do not have a progressive condition and hence will return completely to normal when their exposure is stopped. In most cases such men will attain added resistance by regeneration of injured cells during a short rest from exposure, although occasional men probably will be found who cannot work with carbon tetrachloride at all.

University of Pennsylvania School of Medicine.

#### ABSTRACT OF DISCUSSION

DR. PAUL A. DAVIS, Akron, Ohio: The authors have concurred with my experience that 100 parts per million and less is a safe concentration to maintain when the worker spends from eight to ten hours daily in its presence and that carbon tetrachloride can be used safely in industry if proper ventilation is maintained to keep the concentration low. I have seen several cases in which the liver has been involved to such an extent that several months elapsed before the jaundice had disappeared. Cameron and Karunaratne in the *Journal of Pathology and Bacteriology* of Edinburgh have described carbon tetrachloride cirrhosis. The rubber industry in 1916, 1917 and 1918, during the war period when production was at a premium, used carbon tetrachloride indiscriminately in many kinds of mixtures, because it was cheap and an excellent solvent. Ventilation at that time was neglected and there was much sickness. Since that time ventilation has been improved, supervisors have been educated and a lot has been learned about the toxic properties of carbon tetrachloride and how to handle it. Carbon tetrachloride has been guilty in the past of causing considerable temporary disability, for even in nontoxic concentrations it will cause nausea and vomiting in many workers, which means a loss of time from work. Even though the concentration may be only 100 parts per million it nauseates some workers and they must be relieved from work. I have examined hundreds of these individuals without finding any clinical evidence of poisoning so far as laboratory tests are concerned, but nausea and vomiting are still present and I am inclined to believe that the peculiar odor of carbon tetrachloride is a hyperosmic stimulant. Negative laboratory tests for toxicity do not always insure a cure of the conditions complained of. The authors have mentioned a high calcium diet, which is a good suggestion. The industry with which I am associated has furnished milk for these workers and advised them to eat freely of vegetables at home. Female

workers are more sensitive to the vapors and odors of carbon tetrachloride than the male. With the modern methods of ventilation, it is not at all difficult to keep these vapors and odors at a minimum, but carbon tetrachloride, being a non-inflammable solvent, is used more freely and carelessly than other more dangerous solvents.

DR. W. F. VON OETTINGEN, Wilmington, Del.: I should like to ask the authors how many animals they used for each concentration and whether they have any explanation for the stimulating effect of 40 per cent concentrations on the growth. I wonder whether they have found any difference of higher concentrations on the reproduction of male and female animals, and whether younger animals are more or less susceptible than mature animals. I should like to ask them whether, in those slides which were taken from organs during the process of regeneration, they have seen differences in the shape of the regenerated cells that might parallel the reports by MacNider, who correlates these changes with the increased resistance of those animals to chloroform vapors.

DR. W. J. McCONNELL, New York: I should like to ask Dr. Davis what his experience has been in the treatment of men acutely overcome with carbon tetrachloride. I have had reported recently three instances in one organization in which the intern who called for these patients administered epinephrine and all three immediately died. It appears as though the epinephrine is a sufficient stimulant or added stimulant to throw the heart into ventricular fibrillation. There is some evidence that when the heart is already in that condition the epinephrine has been found effective, but apparently in individuals in whom the heart is weak and the pulse irregular it is rather a hazardous type of treatment. I have recommended merely the inhalation of oxygen in those cases. I wonder whether he has had any experience in the treatment of those more acute cases.

DR. HENRY FIELD SMYTH, Philadelphia: I can answer some of Dr. von Oettingen's questions. We set out with the idea of taking twenty-four small animals in each group. Of course, some of these died from infections, but in every group we carried through the experiment in fifteen or sixteen animals. There were four monkeys in each group. As to the explanation of the fertility, and as to whether the effect on fertility involved males more than females, I do not know. Frankly, that was only incidental in the experiment. We kept a large control colony from the same group of rats, and that was our norm. They were fed the same as the other animals and were kept under the same conditions except that they were not put in exposure chambers. I realize that our observations are incomplete. An attempt was made to get all the animals of about the same age, the early adult rat, but pups were born during the experiment and they were somewhat more resistant; whether that was due to the fact that they were pups or to the fact that they had been born of parents under exposure, I am not prepared to say. As to regeneration cells, they were larger than the normal liver cells, with large spherical nuclei, uniformly granular, and in animals submitted to concentrations of 200 parts per million, in many acini these larger cells were recognized as regenerative, because one often sees pretty mitotic figures in them. When the organism was completely regenerated, after being exposed for several months, they practically came back to the normal, but the acini are smaller, with more connective tissue bands. We made recommendations following Dr. Davis's suggestions as to the selection of workers. We did not go any further because we thought his selections were excellent and were based on experience in industry.

DR. PAUL A. DAVIS, Akron, Ohio: The doctor asked a question of me concerning the use of epinephrine in carbon tetrachloride cases. If the case is acute and the patient unconscious, my treatment is to give intravenous calcium glutinate at once and then get a heart reading if possible. If the patient has a myocarditis, epinephrine should not be given. As to the definite procedure, one ought to know the heart condition before ever doing anything about it, and I think that if a man has reached the stage of narcosis from carbon tetrachloride, has an acute acidosis, and his heart muscles are in such a bad condition, one should not push them up by giving epinephrine. If he is not unconscious, plenty of fresh air should be given. Inhalations of oxygen with 2 per cent carbon dioxide after that is simply an after-treatment.

## SECONDARY RESECTIONS IN RECURRING CARCINOMA OF THE COLON

J. W. THOMPSON, M.D.  
ST. LOUIS

Carcinoma of the colon is a very common lesion, which occurs at all ages. In approximately 50 per cent of all cases encountered the disease has advanced beyond hope of surgical relief. There is an operative mortality varying from 5 to 35 per cent. Frequently the recovery of the patient is stormy, and in lesions of the rectum and lower part of the colon there is all too often the mutilation and social isolation associated with permanent colostomy. In growths more proximally situated, the problem of colostomy is avoided but the frequency of recurrence is greater. Metastasis to the liver and to regional lymphatic channels is always a specter which haunts the lives of those individuals fortunate enough to survive operation. The outlook for a patient proved to have even an operable carcinoma of the colon is, to say the most, not greatly encouraging.

Fig. 1 (case 1).—Microscopic section of first tumor. Edge of primary circumscribed ulcerating carcinoma arising in the mucosa of the pelvic colon with early extension of malignant glands into the submucosa and partly through the muscle coats. The mucosa shows a sudden change (A) from hypertrophic colon mucosa (B) to well differentiated carcinoma. There are a very few malignant glands beneath the peritoneum of the mass of fat tissue under the serosa (C). This tumor was excised wide of the section shown.

This statement is true despite the tremendous amount of propaganda put forth in an attempt to get earlier diagnoses of abdominal or other malignant conditions.

The surgeon who frequently operates for cancer of the colon is always hopeful that his ministrations have been successful, but in many instances recurrence takes place so soon after operation that the difficulty of complete removal of the primary growth is a distinct challenge to the advisability of any attempt to eradicate the disease. The attitude of mind of many practitioners when confronted with a patient in whom a definite diagnosis of a gastro-intestinal malignant growth is made is frequently one of complete hopelessness. Because of this attitude it is difficult to persuade patients to be operated on. The problem is even more difficult when one is faced with the frank presence of recurrence. It

is my opinion that in lesions of the colon in which there is not definite evidence of metastasis in the liver, recurrence in or about the site of previous operative intervention should not deter one from reexploration with a second attempt at removal of the neoplasm. Such cases are admittedly few and are so rare that, when encountered, they should be reported in order to combat the tendency to futile surrender when faced with the possibility of a recurrent carcinoma in a patient otherwise in good or fair general physical state. It is my purpose in this paper to present a small series of such cases in which a second resection of the large bowel has been successfully performed for recurrence of malignant lesions.

Subsequent to apparently complete removal of a colonic lesion the growth may recur at the line of anastomosis, in the operative incision or in the regional lymph nodes, or it may appear in distant organs as the result of metastatic emboli. Recurrence by implantation from abdominal tumors, especially in the exteriorization type of procedure, is a well recognized hazard. The return of many malignant tumors usually is prompt and local, but many years may elapse between the primary removal and the appearance of a recurrence. This phenomenon is more striking in other organs than the gastro-intestinal tract. Thus Ewing<sup>1</sup> records cases wherein thirty years elapsed between primary operation and recurrence in breast cancer, twenty-one years in rectal cancer, and fifteen years in uterine cancer. He quotes Gross as having performed twenty-two operations in fifty-four recurrent tumors in a case of sarcoma of the breast during four years, the patient finally recovering. Thus ample precedent has been established in suggesting that renewed attempts be made completely to extirpate growths which have a tendency to return in a localized area of the large bowel.

Recurrent tumors in the great majority of cases arise from cells or portions of the tumor that have escaped removal. Microscopic section of specimens removed at operation reveal that the knife has passed through strands of tumor tissue or vessels containing tumor cells. For this reason it has always been the practice of abdominal surgeons in performing resections of the intestinal tract to remove a wide portion of normal appearing bowel above and below the primary growth. Serial sections of the normal appearing bowel wall will frequently show that there are strands of cells left behind, and with the abdomen sewed up and the patient returned to the room there is little to do except wait for the possibility and almost certainty of recurrence. Arising from remnants of the original growth recurrence is usually prompt, multiple, in the line of incision or nearby, and of the same type as the original growth, or more malignant. Yet there are many cases which remain dormant for years, and there is always the possibility that the defensive forces of the body will isolate and destroy the few remaining cells by enveloping them in a wall of fibrous tissue proliferation. According to Ewing:

The many instances in which partial removal of malignant tumors has been followed by regression of the remnant, as in ovarian carcinoma and in chorioma, indicate that the mechanical disturbance of nutrition, or removal of local sources of growth stimulus, or the general relief of the organism from toxic products, turn the balance in favor of the patient, and lead to absorption of the tumor cells. Thus tumors in rats sometimes regress after hemorrhagic infiltration following

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

The author is indebted to Dr. H. W. Soper for access to his case records, to Dr. E. V. M. Mastin for his permission to include case 3 in the series herein reported, and to Dr. Walter J. Siebert, pathologist of DePaul Hospital, for his careful study of the tissues microscopically and for helpful suggestions.

1. Ewing, James: *Neoplastic Diseases*, ed. 3, Philadelphia, W. B. Saunders Company, 1927, chapter 4.

crushing trauma. The same factors may be assumed to retard the growth in more malignant tumors which spring up at varying periods after incomplete removal.

In one of the cases presented in this series the original removal of the primary growth seemed quite adequate, and after reoperation for recurrence, had the abdomen not borne the scars of previous operations, the growth present at the secondary session could easily have been deemed the primary one. There was no evidence of metastasis to the regional lymph nodes, the adjacent peritoneal surfaces or the distant viscera, particularly the liver. This unusual finding prompted a review of the literature on recurrence of colonic malignant growths and led to the question as to whether or not the second growth might not be an entirely new and independent one. Could it have been that there was in this patient's organism some stimulus which provoked the development of the second growth in the same manner and in the same site in which the first tumor developed? The specimen removed at the first operation was sectioned serially above and below the growth and no microscopic evidence of incomplete removal was seen. The layers of the intestinal wall appeared to be entirely normal. There was at one place an extension of the growth through the intestinal wall to the peritoneal covering immediately below the growth, but this had been removed in toto with the growth and a wide wedge-shaped piece of the mesentery. Consequently one was impressed with the appearance of the second growth, which was freely movable, entirely without attachment to the adjacent peritoneum or evidence in the gross lymph nodular involvement. It appeared to be a "brand new tumor." The remainder of the abdominal viscera and lymphatics appeared to be free from involvement.

Ewing,<sup>1</sup> in discussing the problem of recurrence, states the possibility of a tumor exerting a pervasive formative influence, leaving the surrounding tissues in a state of excitation with a momentum toward neoplastic growth, so that after removal of a tumor the adjacent tissues give origin to a new tumor. This somewhat vague conception is vigorously opposed by other authorities and cannot be reconciled with the theory of the origin of carcinoma from isolated cell groups. Yet there are considerations that render it inadvisable to discard such a theory of recurrences. This question is closely related to that of the influence of tumor growth on surrounding tissues and to that of the multiple origin of tumors of the same organ. Attention has been called to the fact that some tumors advance by gradual lateral extension over previously normal cells, so that removal at one stage of this extension may leave cells which later reveal their momentum toward tumor growth. The local predisposition to tumor growth may extend over a considerable area, in all of which a neoplasm does not reveal itself at once but develops in several stages or foci. Such conditions are clearly revealed in neurofibromas, and, according to Hauser,<sup>2</sup> with various carcinomas, especially those of the gastro-intestinal tract.

It is well known that tumors of various organs, including the colon, may be multiple. Combinations of multiplicity in the different systems as well as in individual organs or viscera are likewise noted. Warren and Gates,<sup>3</sup> in an exhaustive review of the literature

of multiple primary malignant lesions in the year 1932, collected from the literature 1,259 cases which were identified with accuracy. They conclude that the frequency of multiple malignancy is 1.84 per cent of cancer cases. Multiple cancers occur at approximately the same age as single cancers. Multiple malignant tumors occur more frequently than can be explained on the basis of chance. This may be explained by a predisposition or susceptibility to cancer in certain persons, or the action of some factor or stimulus favoring the development of a malignant growth. The nature of this predisposition is as yet unknown and in the limited space available for this presentation cannot be adequately discussed. Those interested in pursuing the subject further are referred to the excellent article by the aforementioned authors.

The question of whether or not the lesions are true recurrences or new primary growths need not overshadow the practical importance in the clinical field of judicious attempts to relieve the patient of his disease. The general attitude of hopelessness expressed by many practitioners when confronted with patients who have manifestations of recurrence should be combated. There is nothing to be gained by telling the patient that,

Fig. 2 (case 1).—Microscopic section of second cancer. "Recurrence" at the site of the anastomosis following the wide resection of the cancer. A shows a small mass of cancer cells in the serosa, which may be a possible source of the recurrent tumor. This tumor, however, shows many characteristics of a primary carcinoma. It appears to commence in the mucosa and to extend through the submucosa into the muscularis. There was no evidence of lymph node involvement in the widely excised tissue. The involvement of the serosa is limited strictly to the area shown here.

because the lesion has apparently returned, his cause is lost and he must immediately prepare for the inevitable. Provided there is no definite evidence of hopeless metastasis in the lungs or in the liver, recurring symptoms of obstruction or of blood in the stools, either in gross amounts or determinable by the guaiac test, should suggest reexploration of the patient's abdomen and examination for the possibility of further resection or palliation rather than immediate and definite condemnation to a certain slow and extremely obnoxious manner of death. It is with the hope of encouraging others to adopt a positive instead of a negative attitude toward such cases that this paper is presented.

In spite of the fact that the literature on multiple malignant lesions is rather extensive, as a perusal of the review by Warren and Gates will reveal, there is little or no mention of the surgical removal of recurrent lesions, although multiple lesions of the bowel have been noted and frequently removed. Bargen and Rankin<sup>4</sup> in 1930 reported a series of sixteen cases of multiple carcinomas of the large intestine, but in none of these

was there mentioned the problem of local recurrence versus multiplicity. Rankin<sup>5</sup> informs me that he has attempted secondary removal in some cases and quotes Judd as having made similar attempts, with little success. This is to be expected but should not lead to absolute denial of any possible chance of further relief or palliation to be obtained by secondary procedures.

Before multiple carcinomas can be classified as separate and distinct lesions, Billroth's postulates have to be considered: (1) The two growths must show distinct histologic differences, which must be so pronounced as to exclude the possibility that they are of the same origin but in different stages of development, (2) each growth must spring from its parent epithelium, and (3) each growth must be held responsible for its own group of metastatic growth. Mercanton<sup>6</sup> added to these postulates the following qualification: "If after removal of two carcinomas the patient remains free from disease, the two growths must have been inde-

pendent else there should have been other metastasis." It is evident that in carcinomas arising from the intestinal epithelium the first of Billroth's postulates cannot well be fulfilled. Moreover, since carcinomatous degeneration of multiple intestinal polypi is entirely likely, it seems that this postulate need not be fulfilled in identifying multiple independent carcinomas of the intestine. Thus it may be postulated that growths which return at the site of operation, no matter what the intervening length of time, may be open to the question of difference between true recurrence or of a new independent primary tumor actuated by the identical stimuli that produced the first one. The latter hypothesis would seem to hold wherein the second growth had all the gross and microscopic characteristics of an independent neoplasm. Such was apparently the fact in case 1. In those instances in which the secondary or multiple

growth occurred at a point distant from the original lesion after a lapse of many years, such tumors must reasonably be classified as new and independent lesions. There have been but few such cases reported in surgical literature. Klingenstein<sup>7</sup> reported a case in which partial colectomy for carcinoma of the transverse colon was done in 1920, of the sigmoid in 1926, and of the ascending colon in 1934. Pfeiffer,<sup>8</sup> in discussing this case, stated that such an instance of successive independent carcinoma of the bowel was unique in his personal experience. Barga and Rankin<sup>9</sup> have reported a case of three successive carcinomas of the colon followed by sarcoma of the uterus. Dowden<sup>10</sup> relates a case of carcinoma of the pelvic colon which he resected, followed in three years by recurrence in the rectum, for which colostomy was done. Subsequently in one year there was a malignant stricture of the small intestine, which he resected. This patient died six years after the first operation from recurrence at the colostomy opening. Lilienthal<sup>11</sup> wrote of "cancer tendency" in reporting a case of carcinoma of the colon occurring in a patient nearly twenty years after extirpation of a similar tumor. Other than these brief reports of cases recurring after a lapse of years there has been no extensive series reported in the literature, and it is hoped that this report will result in the compilation of those in which operation has been performed so that more light may be thrown on the advisability of reoperation in such cases.

#### REPORT OF CASES

CASE 1.—W. J. K., a man, aged 51, was brought into the DePaul Hospital Dec. 30, 1931, in an acutely ill condition. He stated that in the first part of November 1931 he had noted for the first time that the bowels were constipated. On the advice of neighbors and through reading advertisements, coupled with suggestions heard over the radio, he had taken coarse cereals such as bran flakes to give more roughage in the bowel. He had little success with this and found it necessary to take an occasional dose of epsom salt to secure adequate elimination. The constipation became gradually worse, yet he persisted with the roughage and bran until the abdomen became swollen and distended with gas. He was nauseated and vomited; there was absolutely no bowel movement or passage of flatus for a period of forty-eight hours prior to his admission to the hospital. On examination he was in generally good physical condition. The blood pressure was 130 systolic, 80 diastolic. The urine was normal. The erythrocytes numbered 4,500,000 per cubic millimeter. Hemoglobin was 85 per cent Sahli. The Kline reaction was negative. A plain roentgenogram of the abdomen revealed an enormously distended large intestine with some distention of the small intestinal coils. The cecum could be outlined as a greatly distended pocket of gas. A diagnosis of obstructive lesion of the large intestine was made and immediate cecostomy was advised. The patient was prepared with intravenous infusion of saline solution.

Operation was performed December 30, under 200 mg. of procaine crystals dissolved in 3 cc. of spinal fluid. The incision

pendent else there should have been other metastasis." It is evident that in carcinomas arising from the intestinal epithelium the first of Billroth's postulates cannot well be fulfilled. Moreover, since carcinomatous degeneration of multiple intestinal polypi is entirely likely, it seems that this postulate need not be fulfilled in identifying multiple independent carcinomas of the intestine. Thus it may be postulated that growths which return at the site of operation, no matter what the intervening length of time, may be open to the question of difference between true recurrence or of a new independent primary tumor actuated by the identical stimuli that produced the first one. The latter hypothesis would seem to hold wherein the second growth had all the gross and microscopic characteristics of an independent neoplasm. Such was apparently the fact in case 1. In those instances in which the secondary or multiple

was made in the lower right quadrant and the cecum presented itself distended to the size of a football. The gas was permitted to escape by puncturing the cecal wall with a needle and then a cecostomy was made, a number 24 colon tube being inserted in the bowel after the method of Witzel. The colon tube was brought out through a small stab incision lateral to the main incision, which was closed in anatomic layers without drainage.

The patient's subsequent course was quite satisfactory. Irrigation of the cecostomy opening with copious quantities of water brought forth large amounts of bran that had been impacted along the bowel all the way down to the pelvic colon, which proved to be the site of the obstruction as determined by subsequent examination with the barium sulfate enema. When the bowel had been thoroughly cleansed and had resumed its normal caliber and tonus, resection of the growth was elected. Operation was done Jan. 14, 1932, again under spinal anesthesia. The growth was annular and constricting in type, situated in the pelvic colon. There was no evidence of metastasis in the liver or grossly in the regional lymphatics. A segment of colon approximately 6 or 7 inches (15 or 18 cm.) was resected, a wide margin of normal appearing and normal feeling intestine being taken above and below the growth. Because the bowel was somewhat redundant, this was easily accomplished. A wedge-shaped piece of mesentery including the regional lymph nodes was included and removed in one piece in toto. An end-to-end anastomosis was performed, Dulox catgut reinforced with linen being used. The abdomen was closed in layers. The cecostomy tube was permitted to remain for purposes of decompression. The patient made an uneventful recovery; the wound healed by first intention and the cecostomy tube was removed on the sixth day after he had several normal bowel movements. The cecal fistula soon healed and the patient was dismissed from the hospital in good condition on the thirtieth day following his initial admission.

His subsequent course was quite interesting. A barium sulfate enema, March 30, showed a normal appearance with smooth adequately calibered bowel at the juncture of the iliac and pelvic colon. The man had gained in weight, resumed his occupation and considered himself well. In October 1934, twenty-two months after his operation, he returned with symptoms of constipation similar to those he experienced prior to his initial illness. Proctoscopic examination showed nothing abnormal. A barium sulfate enema, however, disclosed evidence of obstruction at the juncture of the iliac and pelvic colon with a filling defect and palpable mass. The manifestations were considered to be characteristic of carcinoma and immediate reoperation was advised and accepted. Routine examination of the blood and urine showed them to be normal. The man weighed 177 pounds (80 Kg.) and appeared to be in the best of health.

Secondary operation, October 15, through a left rectus incision, again with spinal anesthesia, revealed a napkin-ring type of growth identical in appearance with the one previously encountered. After mobilization of the tumor it was possible to resect it with approximately 2 inches (5 cm.) of normal mucous membrane on either side of the malignant stricture, a segment of bowel being resected again about 5 or 6 inches (13 or 15 cm.) in length. An end-to-end anastomosis was made and all raw surface was peritonealized. A segment of the mesentery was again removed. Careful preliminary exploration of the abdomen did not reveal any sign of metastasis in the liver or any peritoneal surface. A cecostomy was not deemed necessary. The incision was closed in layers, a small Penrose cigaret drain being left down to the suture line lateral to the intestinal wall.

The patient again had an uneventful convalescence. He has remained well to date, and repeated examinations of the stool for occult blood and examination of the bowel by barium sulfate enemas have failed to disclose any further evidence of recurrence (figs. 1, 2 and 3).

CASE 2.—C. K., a man, aged 54, came to the attention of Dr. H. W. Soper in July 1917. His chief complaints at that time were diarrhea, loss of weight, tenesmus, and mucus in the stools. In his youth he had contracted a hard chancre, for which vigorous treatment had been given. On physical examination he appeared anemic and acutely ill. The erythrocyte count was 3,250,000 and the hemoglobin (Sahli) was 35 per cent. There was a palpable mass in the right lower quadrant.

A barium sulfate enema revealed a filling defect at the cecum. *Endamoeba histolytica* was found in the stools. A diagnosis of carcinoma of the cecum and amebic dysentery was made and he was referred to the Mayo Clinic for surgical treatment. October 9, Dr. W. J. Mayo removed the cecum, ascending colon and terminal ileum. The lesion was described as an adenocarcinoma of the cecum and ascending colon with involvement of the regional lymph nodes, which were removed. Because of this a poor prognosis was given.

During the intervening years between 1917 and 1930 the patient had been observed at frequent periods by Dr. R. W. Mills, who checked the colon for recurrence by means of barium sulfate enemas. They were consistently negative. After the death of Dr. Mills in 1924 the man did not return as frequently as formerly but considered himself quite well.

In the fall of 1929, at the age of 68, because of bleeding from the large bowel, he was subjected elsewhere to hemorrhoidectomy. Immediate recurrence of notable bright red bleeding in the stools following this procedure led him to consult Dr. Soper for determination of the source of the hemorrhage. Examination of the patient at this time showed him to be in remarkably good general condition. There were 4.75 million erythrocytes per cubic millimeter in the blood, and hemoglobin (Sahli) 85 per cent. Occult blood was present in the stools

Fig. 4 (case 2).—Microscopic section showing a primary pedunculated papillary adenocarcinoma arising in the transverse colon thirteen years after the removal of an ulcerating adenocarcinoma of the cecum with lymph node involvement. This tumor shows an abrupt transition of hypertrophic into neoplastic epithelium, A. The carcinoma begins in the mucosa and extends deeply into the submucosa and to a less degree into the muscularis. This is distinctly a primary carcinoma. Examination of the colon at both operations failed to reveal the presence of polyps.

(guaiac test). A barium sulfate enema revealed a small filling defect in the transverse colon just distal to the splenic flexure. A diagnosis of carcinoma of the transverse colon was made and the patient was advised to submit to immediate operation.

Operation (J. W. T.) was performed Jan. 28, 1930, at St. Luke's Hospital under spinal anesthesia induced by 200 mg. of procaine crystals. An upper left rectus incision was made and the liver first explored for metastases. None were found. The peritoneal surfaces were likewise free. The site of the previous resection (done in 1917) was quite free from adhesions. In the distal transverse colon a carcinoma the size of a dollar (38 mm.) was found. The wall of the bowel was free from extension to the peritoneal surface. The segment of bowel containing the carcinoma was freed, together with a fan-shaped wedge of mesentery and the freed loop of intestine fixed in Rankin's clamp and the involved segment of intestine severed with the actual electric cautery. The ends of the intestine were reunited in the aseptic manner described by Rankin by suturing the intestinal walls together with Dulox catgut over the clamp. The line of anastomosis was further protected by reinforcement with silk sutures, and additional protection was supplied by placing adjacent fat along the suture line fixed by interrupted silk sutures. The rent in the mesentery was

repaired and the abdomen was closed in layers without drainage. The postoperative course of the patient was uneventful, with the exception of a slight superficial wound infection.

The patient's subsequent course has been quite satisfactory. Repeated examinations of the stools for occult blood have always proved negative. The barium sulfate enema test shows that there is perfect canalization of the lumen of the colon with a good smooth contour of the colonic wall at the site of anastomosis, with the caliber of the lumen the same size as that of the rest of the intestine in the transverse colon. During the interim the patient has lived a useful life and was forced to retire from his occupation owing to the development of coronary sclerosis with symptoms of angina pectoris. He was still living in a fair degree of comfort in 1936 at the age of 75.

CASE 3.—M. B., a man, aged 36, came to the attention of Drs. Soper and Mills in 1918. He complained of pain in the midepigastrium radiating in all directions. The pain came on after eating and lasted for about fifteen minutes, cramplike in character. The bowels had been constipated. His weight was 137 pounds (62 Kg.), a loss of nearly 20 pounds (9 Kg.). These symptoms had been progressing for approximately one year. There had been no blood noted in the stools. Examination of the urine was negative. The erythrocyte count was 4,000,000. Hemoglobin (Sahli) was 60 per cent and the Wassermann reaction was negative. Gastro-intestinal x-ray examination by Dr. Mills revealed a filling defect in the proximal transverse colon.

Fig. 5 (case 3).—A "true" recurrence of a poorly differentiated carcinoma of the colon in which a large cancerous mass (A) remained behind in the serosa after an incomplete resection nine years previously. The tumor has extended from the serosa, through the muscularis into the submucosa, and finally into the otherwise normal mucosa. The dark areas (M) are masses of cancer cells that have invaded the base of the otherwise normal mucosa. S shows similar masses in the submucosa and T shows masses that have invaded the muscularis. The invasion of the muscularis is considerably more extensive than in the submucosa. The longitudinal muscle layer is almost completely destroyed by the cancer.

The first operation, Nov. 20, 1918, at St. Luke's Hospital by Dr. H. G. Mudd, through a right rectus incision revealed a large tumor of the transverse colon. The lesion was annular, surrounding the entire intestine and attached slightly to the gallbladder. The intestine was freed from its mesentery for 3 inches (7.5 cm.) above and below the lesion, which was then severed between clamps with the actual cautery. The ends of the bowel were turned in and a lateral anastomosis was made. There was no evident lymph node involvement. Two nodes were removed and proved to be simple hyperplasia of inflammation. The lesion itself was an adenocarcinoma (sections of tissue not available).

The patient remained well and resumed his work as a pedler. He returned for examination from time to time and in February 1927 a small mass was found in the right upper quadrant. His weight then was 147 pounds (66.7 Kg.) and his general condition good. The erythrocytes were 4,000,000 and the hemoglobin (Sahli) was 78 per cent. There was a four plus guaiac test for occult blood in the stools. Gastro-intestinal x-ray examination revealed a carcinomatous filling defect in the distal ascending colon, the lesion appearing to be on the proximal side of the anastomosis made in 1918. The urine was normal and the Wassermann reaction was again negative. Surgical exploration was recommended.

At a secondary operation, March 15, 1927, at St. Luke's Hospital the abdomen was opened to the left of the old scar. There was a large mass in the region of the ascending colon, adherent to the liver, abdominal wall, gallbladder, duodenum and head of the pancreas. The gallbladder contained stones. After careful dissection of the adhesions the mass was mobilized and the ascending colon and a portion of the transverse colon were resected together with the terminal ileum, cecum and appendix. As many as possible of the regional lymph nodes were removed. The continuity was added, a 20 French catheter being placed into the terminal ileum. A piece of omentum was used to protect the anastomosis. One Penrose drain was left in the upper angle of the wound, which was closed in layers around the drain.

The patient made an uneventful recovery from this procedure after overcoming the usual postoperative hazards of shock and wound infection but encountered difficulties in October 1927, when he suffered an attack of acute small intestine obstruction, which made it necessary to reopen the abdomen to relieve the obstruction produced by an adhesion band. Following this procedure he has remained well, and when last heard from in 1936 he was in good general condition.

#### COMMENT

These three patients present entirely different phases of the clinical problem under discussion. There was no doubt about the second diagnosis of recurrence in case 1, or possibly a new primary carcinoma similar to the initial lesion. In case 2 one cannot regard the lesion of the transverse colon occurring thirteen years after the resection of the right half of the colon as a true recurrence. This growth should be classified as a new primary carcinoma of the bowel (fig. 4). Case 3 is undoubtedly an example of true recurrence. The fact that these three patients survived secondary resections of the colon and have led useful lives subsequently should encourage one to make some effort to remove recurring or multiple growths from the colon instead of assuming an attitude of utter hopelessness when faced with such situations. One is not always rewarded with such success, for in two other personal cases in which symptoms of weight loss, occult blood in the stools, and demonstrable filling defect in the colon led to reexploration of the abdomen, hopeless metastasis in the liver defeated the attempts to forestall the inevitable. Such experiences should not, however, deter one from making the attempt in every case in which the general condition of the patient justifies it.

#### SUMMARY AND CONCLUSIONS

1. Recurring carcinoma of the colon is not invariably a hopeless lesion and should not be prognosticated as such.
2. Multiple malignant lesions of the colon are probably not as rare as commonly believed. They may occur simultaneously or develop after a period of many years.
3. A more positive attitude of mind in the diagnosis and surgical management of malignant lesions of the gastro-intestinal tract should be encouraged to afford earlier recognition of primary lesions and to lend hope for possible surgical cure or further palliation for secondary neoplasms.

#### ABSTRACT OF DISCUSSION

DR. CLAUDE J. HUNT, Kansas City, Mo.: Two points stand out in this presentation worthy of emphasis: first, the importance of early operation in primary or secondary malignant lesions of the colon; second, that more than one carcinoma may exist simultaneously or at widely separated periods of time in the colon, which are separate and distinct and have no relation to one another. Early operation on a primary or secondary

growth offers two distinct advantages to the patient: the opportunity of successful removal of the lesion, as was accomplished in these cases, and the alternative of sometimes anastomosing around an inoperable mass, thereby detouring the fecal current and limiting to a minimum subsequent infection and hemorrhage and eliminating a later colostomy with its disagreeable features. Infection, hemorrhage and secondary anemia contribute much to the discomfort of the patient and hasten the progress of the disease; thus, with a detoured fecal current patients live much longer and are more comfortable, and obstruction is less likely. I cannot fail to speak of the merits of an anastomosis of this nature as a palliative operation worthy of great consideration. By such a procedure some indurated inflammatory masses may recede and subsequently become operable. The cases in this presentation are most probably secondary independent growths. Primary recurrence would have manifested itself by local recurrence at or near the site of the original bowel lesion and would have shown extensive local metastasis as well as binding down of the bowel at the primary site of extensive adhesions and contractures. My experience with recurrent carcinomas of the large bowel has been that they are decidedly inoperable, owing to local extension and to visceral and glandular metastasis. I have done an anastomosis around the inoperable mass when possible. When obstruction was present or the location of the lesion prevented anastomosis, colostomy was performed. Considering these as secondary lesions, one must speculate on the possible causative factor of multiple carcinoma of the colon. It is not likely that carcinoma develops on normal colonic mucosa but that some abnormal benign lesion, as adenomas or polypi, plays a part in their development. These benign lesions are known to be commonly distributed along the colonic mucosa. Bardenhauer and others first spoke of the malignant change in adenomatous cells, and Rankin and Fitzgibbon demonstrated that certain colonic polypi had a tendency to undergo malignant change. Many such cases are on record. Billroth's postulates as to secondary malignant lesions are interesting but hardly tenable for colonic carcinoma.

DR. C. F. DIXON, Rochester, Minn.: Dr. Thompson's presentation interests me. His material is worthy of being made a matter of record, as it emphasizes that the development of a malignant process at the site of a former operation for neoplastic growth does not necessarily indicate that the patient is doomed. Whether such a lesion is a recurrence or another primary growth is a matter of conjecture. It is my opinion that, if a patient has no sign of local recurrence of the disease for two or three years, any malignant tumor that develops subsequently should be considered to be an independent process. However, it has been shown that rests of malignant cells may remain more or less dormant for a number of years. The problem of particular interest in this discussion concerns the feasibility of subsequent resection because of carcinoma of the bowel. If there is no evidence of metastasis to the liver and the patient's condition is "fair" or "good," I feel that an attempt should be made to remove the malignant process by resecting the intestine. When there is doubt about the condition of the liver, the functional tests will be of great value in reaching a correct decision, since there would certainly be an appreciable impairment of the function of the liver in most cases in which marked metastasis to the liver has occurred. My feeling regarding the justification of subsequent resection of the intestine for carcinoma is substantiated by the results obtained in eight cases in which the patients' lives were extended for years by multiple operations in which segments of the colon were removed. Two patients had several resections of the bowel and lived about two and nine years respectively, after the last operation, but in neither case was death due to a malignant process. I agree with Dr. Rankin and Dr. Hunt that rehabilitation of the patient before operation is of inestimable value; however, I do not subscribe to Dr. Rankin's present idea that preoperative vaccination is of no value, nor do I concur in his opinion that the administration of vaccine is a dangerous procedure. At the clinic we have employed intraperitoneal vaccination as a measure for the prevention of peritonitis in more than 3,000 instances, and since its use the death rate from peritonitis has decreased appreciably. As closely as we are able to estimate, we now lose one patient from peritonitis where formerly three

succumbed to it. Of course the technic in carrying out any surgical procedure is important, but I am certain that my surgical technic is no better than that of those of the same institution who have gone before me; nevertheless, the mortality has been greatly reduced. It would hardly seem fair to say that intraperitoneal vaccination is dangerous, since in 3,000 or more instances there has not been a single death that could be attributed to that procedure.

## THE TREATMENT OF PRIMARY MALIGNANT CHANGES OF THE BONE

BY RADICAL RESECTION WITH BONE GRAFT REPLACEMENT

FRED H. ALBEE, M.D.  
NEW YORK

The treatment of malignant growths of the bone, especially primary bone sarcoma, is still desperately unsatisfactory, despite strenuous efforts to its improvement. Most radical amputations, preceded and followed by x-ray and radium therapy, are able to secure lasting results in only a small number of cases. Metastases in the lungs may develop within a longer or shorter time after the amputation, quite often without involvement of the regional lymph nodes.

The uncertainty of the outcome in these radical and crippling operations, the severe psychic trauma that they usually represent for the patient, the difficulty of applying an artificial limb after exarticulation in the hip joint, all have led to less radical surgical procedures, if possible, applied earlier, which, still aiming at eradication of the malignant tumor, are an attempt to save the extremity in its usefulness.

I do not claim any miracles. I think that the therapeutic problem of malignant growths of the bone is still unsolved. Time and greater clinical material will have to show whether my method is definitely superior to any other actually in use, but from a relatively small number of cases I obtained the certain impression that it can compare quite favorably with the surgical routine treatment and was so decidedly advantageous in some of the cases that its value cannot be underestimated. The method consists of a radical resection of the tumor followed by a plastic bone graft replacement operation. I am presenting here briefly thirteen cases of malignant growths of the bone. Three involved the shoulder region, seven the lower end of the femur and three the shaft and lower end of the tibia.

### SHOULDER REGION (THREE CASES)

The following case has been reported in a previous article (1921) in which special emphasis was put on the operative technic of restoration of shoulder joint function. The case is presented again here with a follow up of almost seventeen years.

CASE 1.—A woman, aged 25, complained of constant pain in the left shoulder, especially at night, and reported a slight loss of weight. The roentgenogram revealed a destructive lesion in the upper third of the shaft of the humerus with expansion into the soft tissues. The clinical and x-ray diagnosis of osteosarcoma was made and later on confirmed and specified histologically as osteosarcoma with malignant activity. Surgical removal was decided on and performed.

The operation consisted in the resection of the head and 5 inches (12.5 cm.) of the upper end of the shaft with replacement by a long piece of the fibula. More in detail, the opera-

Read before the Section on Orthopedic Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

tive procedure was as follows: The patient was placed on the Albee table and traction was applied to the left arm, which was kept in the same position throughout the entire operation. The tumor was exposed and a frozen section made. The soft parts were separated from the bone by blunt and sharp dissection, care being taken to keep well outside the area of the new growth. The shaft was completely severed by means of a Gigli saw, about  $4\frac{1}{2}$  inches (11 cm.) from the upper extremity of the humerus, well below the tumor. After removal of the upper fragment, the upper end of the humeral shaft was prepared for the reception of the fibula transplant. The marrow cavity was slightly enlarged and by means of the twin saw a groove was cut in the shaft for about one-half inch (1.3 cm.). The upper end of the fibula was then removed through a posterior incision (because the fibula can be exposed much more easily from behind and the peroneal nerve can be brought better in safety). With the Gigli saw a piece of the fibula was removed so as to exceed the length of the removed humeral fragment for about 1 inch. The angular projections on the surface of the fibula shaft were roughly trimmed down

pain in the shoulder on motion. The pain could be relieved by physical therapy and especially by rest. She was last seen about seventeen years after operation. The shoulder was found somewhat lax and the left arm was considerably shorter than the right, but there was good function of the arm; the patient was even able to play the piano. Roentgenograms four years after operation showed that a part of the fibula had become resorbed at the site of insertion into the humerus, but there was sufficient periosteal bone formation around this area to prevent pseudarthrosis. Another picture, seven years after the operation, revealed good consolidation between graft and host. The head of the fibula was still well implanted below the acromion. There was no sign of local recurrence of the tumor.

The same form of plastic shoulder repair after radical excision of the upper end of the humerus was carried out in other instances.

CASE 2.—A girl, aged 14 years, had been complaining of some pain in her right shoulder for about half a year; she

Fig. 1 (case 2).—Giant cell sarcoma, with the upper end of the humerus resected and replaced by fibula grafts. No signs of tumor recurrence.

with the motor saw, and the diameter of the shaft was thus made slightly smaller at the lower end so that it might be easily inserted into the humeral shaft. Then the fibula transplant was driven into the humerus until the head just engaged under the acromion process, while traction was exerted on the arm in order to restore the normal length of the upper arm. The upper end of the humerus was drilled in such a manner that graft and host were pierced completely. A kangaroo tendon was passed through the drill canal and tied securely.

The musculature was quite well preserved with the exception of the distal end of the pectoralis major, which had been resected for about one-half inch (1.25 cm.) to keep away from the tumor. It was just possible to dissect out the various muscles, which were fastened each in the place of its normal insertion on the head and neck of the fibula by means of small kangaroo tendons passed through drill holes.

The arm was immobilized in a plaster cast for three months. There was solid bony union and the patient was encouraged to use the arm. She slipped and fell six months after operation. Roentgenograms revealed a fracture through the fibula graft. The arm was again immobilized and firm bony consolidation was present about ten weeks later. Under physical therapy she regained so much use of the operated arm that she could play golf with it and drive a car. She complained of occasional

recently fell and since then the pain in the shoulder had been aggravated. Roentgenograms (fig. 1) at the time of admission showed a destructive lesion at the upper third of the humerus with involvement of the epiphysis. The lesion appeared multi-loculated at the periphery, cystic in the center. The cortical bone was perforated on the inner side and the surrounding soft tissues were invaded. The picture was suggestive of a giant cell tumor with malignant activity. Radical resection of the upper end of the fibula was performed. The pathologic report was giant cell sarcoma showing malignant activity. The patient made a very good recovery. She was seen last two years and nine months after the operation. There were no signs of tumor recurrence. She was complaining of occasional pain in the shoulder, mainly on motion. There was active abduction of the shoulder for about 45 degrees. Passive motion was 75 degrees and active external and internal rotation about 20 degrees. There was no shortening of the extremity.

Roentgenograms on different occasions, up to twenty-eight months after the operation, showed excellent bony union at the site of the implantation. The head of the fibula resting against the lower surface of the acromion revealed some structural changes that suggested functional adaptation. There was considerable increase in the thickness of the grafted fibula, and

at the site of insertion into the humerus a considerable amount of periosteal bone had formed or produced a sharp spur formation. There were absolutely no signs of tumor recurrence almost three years after the operation.

CASE 3.—A youth, aged 17, complained of a sclerosing osteogenic sarcoma of the upper metaphysis of the humerus and a typical sunray structure at the periosteal surface. The upper end of the humerus was resected and a fibula graft inserted. Two months after the operation there were metastases to the spinal cord with flaccid paralysis, and the patient died. There was no local recurrence.

#### KNEE REGION (SIX CASES)

The most frequent localization of bone sarcoma, the region of the knee, and especially the lower end of the femur, was represented in the series by six cases. The localization of the tumor close to or within the epiphysis many times requires the resection of the knee joint. This was done in three cases, and in only one case, in which the tumor was more of diaphyseal localization, could the joint and the lower epiphysis of the femur be saved. The operative procedure in the four was as follows: Under tourniquet the kneejoint is opened by a split patella incision, a motor saw being used. The lower end of the femur is exposed. Great care has to be taken to keep away from the tumor, especially if there is already invasion of the surrounding soft tissues. With a Gigli saw the distal portion of the femur is resected and the upper joint surface of the tibia is freshened by removal of the entire joint cartilage. A strong sliding bone graft is taken from the crest of the tibia of sufficient length to prevent shortening. It is firmly anchored into the distal end of the femur and the proximal end of the tibia with the use of kangaroo tendons passed through drill holes. The sliding graft is reinforced by at least three sliver grafts, which are placed obliquely around so as to form a pyramidal

Fig. 2 (case 4).—Osteogenic sarcoma of the lower end of the femur.

structure with the base at the upper surface of the tibia. The two halves of the patella are also used for reinforcement. The soft tissues are then closed tightly and a hip spica cast used for immobilization.

CASE 4 (fig. 2).—A woman, aged 20, was in a train accident; the right knee was caught between the train and the platform. Two or three weeks later she noticed a small lump on the inner aspect of the knee. She was operated on and a tumor was found and pronounced osteofibroma. She received high voltage roentgen treatment but the tumor recurred rapidly.

Roentgenograms at the time of admission showed a huge densely calcified tumor at the posterior aspect of the lower end of the femur infiltrating the popliteal fossa. The diagnosis was osteogenic sarcoma of periosteal origin.

The lower end of the femur was resected together with the knee joint and replaced by a heavy tibial bone graft. The pathologic report confirmed the roentgenologic diagnosis. The patient was immobilized in plaster casts for one and a half years. More than two and one-half years has elapsed since the operation; the legs are of even length and she is in very good health

Fig. 3 (case 4).—Tumor resected and replaced by sliding tibial bone graft. Note the marked hypertrophy of the graft.

and walks very well. Roentgenograms show a remarkable hypertrophy of the transplanted grafts, and the resected portion of the femur has regenerated to almost the normal thickness (fig. 3).

CASE 5.—A youth, aged 20, had an osteogenic sarcoma of the lower end of the femur, mainly of the periosteal type. The same procedure as in the former cases was carried out and a "gun-pyramide" of tibial bone grafts was erected. The grafts took very well, and only a part of the patella sloughed out. One and a half years has now elapsed since the operation, and the patient is able to put some weight on the extremity. His general condition is very good. The last roentgenograms show very good osteogenesis around the bone graft. There has been a telescoping of the graft along the tibial gutter, which is responsible for a shortening of more than 1 inch. Because of this, the technic has been changed to an end to end mortise of graft into the tibia. There are no roentgenologic signs of tumor recurrence.

CASE 6.—A man, aged 24, with chondrosarcoma of the lower end of the femur, was treated in the same way. The wound over the tibia became infected. A guillotine amputation was performed through the upper third of the femur. Three months after the operation the patient's general condition is very good. There are no signs of local recurrence or tumor metastases.

CASE 7.—A girl, aged 8 years, had a highly malignant osteochondrosarcoma of the lower third of the femoral diaphysis without involvement of the epiphysis. The problem was different from the three cases just reported. The radical resection of the lower end of the femur with its epiphyseal cartilage together with the knee joint would have resulted in a marked shortening in case the patient should survive the operation for years. It was decided, therefore, to resect just the diseased

portion of the diaphysis but to leave the lower epiphyseal cartilage and the lower epiphysis intact. This was done, and a tibial graft was firmly anchored into both fragments of the femur, reinforced by some sliver grafts. The grafts took very nicely, but the patient had a very stormy postoperative course, with several pyemic abscesses and peroneal palsy of the operated leg. She finally recovered and is now able to walk in a short leg brace to prevent foot drop. Frequent roentgenologic control examinations have revealed a very rapid enlargement of the bone graft at the site of resection, and more than two years after the operation the regeneration has led to normal thickness of the bone. There is shortening of the left leg for about 1 inch. This is mainly due to an anterior bowing of the femur and to the accidental dislodging of the bone graft from its femoral mortise by an assistant dropping the leg after the skin wound had been closed at operation. In spite of this, the graft united promptly to the femoral fragment. There was no recurrence.

CASE 8.—A man, aged 32, had a history of having been operated on at Beekman Street Hospital for a giant cell sarcoma of the lower end of the left femur in March 1931 in which the tumor was thoroughly curetted out and the cavity filled with bone chips taken from the tibia. This was followed by high voltage roentgen therapy. On the day of examination at my office there was a marked recurrence of the tumor, as evidenced in the roentgenogram by a large mass at the external femoral condyle and edema. There was marked nocturnal pain and a loss of 15 pounds (6.8 Kg.). The surgical indication was amputation or wide resection. Resection and replacement with a massive tibial bone graft were done at the New York Post-Graduate Hospital Jan. 21, 1932. The patient did not follow instructions and under direction of another physician he left off the splint and broke the graft by walking without support. A union of the fractured graft was obtained. There was no recurrence four years and four months after resection.

CASE 9.—A youth, aged 18, had three months before admission hit his right knee against an iron shelf. This was followed by the knee slipping, and an exploratory arthrotomy was done. There was no internal derangement of the knee joint. Three months after the operation he began to have nocturnal pain, and a pronounced swelling appeared just above the knee. Roentgenograms disclosed what was diagnosed as periosteal sarcoma extending from about 2 inches above the location of the epiphyseal plate upward for about  $3\frac{1}{2}$  inches (8.8 cm.). A biopsy examination resulted in a diagnosis of chondrosarcoma. About 6 inches (15 cm.) of the shaft of the femur was resected, leaving the epiphyseal cartilage and the condyles of the femur intact. A tibial graft of sufficient length and strength was mortised into the center of the upper cut surface of the lower femoral fragment and into the marrow cavity of the upper femoral fragment, the muscles being pulled about the graft carefully. It has now been six months since the operation, and the graft has proliferated. There is no recurrence.

CASE 10.—A girl, aged 8 years, had a tumor (round-cell sarcoma) of six months' duration involving the lower third of the right femur, extending upward from just above the epiphyseal plate. It has been rapidly enlarging in spite of high voltage roentgen therapy and Coley's serum. Resection was done precisely as in case 9. The tibial graft which had to be about  $8\frac{1}{2}$  inches (21.5 cm.) long because of the extensive amount of the femur resected, was mortised into each fragment of the femur. The lower three fourths of it was, however, split with a motor saw and spread precisely as the upper end of a crutch. Each of the prongs of the graft was mortised into the inner and outer border of the cut upper surface of the lower femoral fragment. The upper end of a second graft was placed in the crotch of the first graft and its lower end mortised into the center of the cut surface of the lower femoral fragment. The muscles were then drawn about and between the grafts with great care. The grafts are proliferating. There is no recurrence after six months.

#### TIBIA (THREE CASES)

CASE 11.—A boy, aged 11 years, had throbbing pain, especially at night, in the left tibia. There was no fever. Roentgenograms revealed some fusiform thickening of the middle

of the diaphysis, with sclerosis and slight haziness of the periosteal outline. There was a difference of opinion as to the diagnosis. The lesion was first considered inflammatory by some of the consultants, and biopsy confirmed this diagnosis. The patient disappeared and returned in two months. In this short space of time the tumor had extended through the biopsy hole in the cortex to such a degree that there was no question of its extreme malignant condition. The pathologic report from the resected diaphysis was osteogenic sarcoma, but the roentgenogram suggested more Ewing's tumor. A radical resection of a good 8 inches (20 cm.) from the shaft of the tibia was performed with the preservation of both epiphyseal plates. The graft became broken at the upper end from too early weight bearing. Double wedge-end grafts with sliver grafts beside the fracture junction were inserted, and a firm anchorage of the graft was finally secured without shortening. Two years after the first operation the graft showed roentgenologically some increase in thickness, and the boy was able to bear full weight. Metastases developed in the lungs and the patient died without signs of local recurrence almost two and one-half years after the first operation.

CASE 12.—A woman, aged 49, with generalized Paget's disease of more than twelve years' duration (and nine years under my observation) suddenly complained of pain and swelling at the lower third of the left tibia. There was a tender tumor mass at the inner and posterior aspect, just below the junction of the middle and lower thirds. The tumor was rapidly growing. Roentgenograms taken in an interval of eight months showed first the very typical signs of advanced Paget's disease of the tibia and then an ossified periosteal tumor with sunray structure.

The tumor was resected (pathologic report: osteogenic sarcoma on the basis of osteitis deformans) and a graft taken from the same tibia was used to bridge the defect. About two months after the operation another tumor developed on the left side of the skull, which was considered another sarcoma formation on top of a Paget skull bone. The tumor compressed the brain, and the patient died with cerebral symptoms three months after resection of the tibia. There was no local recurrence at the tibia.

CASE 13 (fig. 4).—A physician, aged 33, with a giant cell tumor of the lower end of the tibia, was first treated by radical curettage, and sliver grafts were put into the cavity for bone formation. There was definite recurrence of the tumor with resorption of the grafts half a year after the operation, associated with nocturnal pain and loss of weight. At this time, the lower 4 inches (10 cm.) of the tibia was resected and the entire joint cartilage of the upper joint surface of the astragalus was removed. Two cortical grafts were firmly inserted with their marrow surfaces together into the astragalus and tied at its upper end with kangaroo tendons passed through drill holes. The grafts took beautifully. It is now nearly a year after the operation; he is still walking with a caliper brace, but the grafts are strong and much enlarged and full weight can be borne on the extremity, even without a brace. There are no signs of recurrence roentgenologically.

This series of thirteen cases, in which malignant growths of the bone were treated by radical resections and bone grafts, permits, despite its relative smallness, a number of definite conclusions. It shows that it is possible, at least in a number of selected cases, to free the patient from a malignant condition of the bone and to preserve a useful extremity. Case 1, presenting a giant cell sarcoma of the upper end of the humerus, has been followed for almost seventeen years without any signs of tumor recurrence. Doubts on the correctness of the tumor diagnosis are not justified because the diagnosis was made on the basis of several slides by a competent pathologist. The diagnosis—giant cell sarcoma—could, of course, suggest the possibility of a giant cell tumor, an essentially benign lesion of the bone. This possibility cannot be ruled out entirely, either for the first or for the second case. But even if the cases were benign giant cell tumors, they were so

markedly advanced and the surrounding soft tissues were found so invaded at the time of operation that the radical procedure with resection was certainly indicated. A curettage in such a weakened condition of the bone would only have led to pathologic fracture and, without any doubt, to recurrence. I shall discuss the question of benign cell tumor more in detail a little later.

The plastic repair of the shoulder with the upper end of the fibula following radical resection, or following badly infected subcapital fracture-dislocation and defect-pseudarthrosis, has proved to be such a gratifying procedure that I can recommend it highly.

Most of my patients have a follow up of around two and one-half years, which is not long enough to judge lasting results in such cases. All the patients were free

mentioned; in case 8, however, the peroneal nerve had to be resected with the tumor, resulting in a foot drop.

Further clinical observation and richer material will have to show whether this method will secure lasting results in bone sarcoma of high malignancy. It seems to be the method of choice in the so-called benign giant cell tumors, however. Every surgeon of some experience knows that these tumors are by no means always as benign as one would think from the term. On the contrary, they are as a rule very resistant to the routine treatment with curet and caustic substances. Local recurrence following curettage is very frequent. More advanced and extensive cases can hardly be benefited by curettage. These cases, most frequently found at the lower end of the femur, are the ideal cases for resection and the plastic repair with the graft pyramid.

Fig. 4 (case 13).—Giant cell tumor of the lower end of the tibia, first curetted ( $B_1$   $B_2$ ) with implantation of sliver grafts, and recurrence ( $C_1$   $C_2$ ). It was then resected and replaced by two cortical bone grafts ( $D_1$   $D_2$ ) implanted into the astragalus. There was no tumor recurrence.

from tumor in the operative area, although in one death occurred two and a half years after the operation of lung metastases (case 11). Two patients died a relatively short time after the operation, one of metastases to the spine with compression of the spinal cord and flaccid paralysis of the lower extremities (case 3) and in the other, a case of Paget's disease, besides the resected sarcoma of the tibia another malignant tumor of the skull developed with brain compression (case 12). There was no local recurrence in either case. This fact is of considerable interest. It shows that it is possible to remove all the tumor even in very extensive malignant changes of the bones. In tumors of diaphyseal localization in juvenile individuals one may even succeed in preserving the epiphyseal plate and the joint. The danger of blood vessel and nerve involvement is apparently not as great as is commonly stated. In my experience tumors of the upper end of the tibia and fibula show early involvement of the tibial vessels. I could keep away from the main vessels in all cases

I think that in no case of benign giant cell tumor should amputation be performed before the plastic restoration of the resected tumor has been tried, and I also feel that this method should be used immediately, as soon as curettage is followed by recurrence. I am quite convinced that with this procedure a great number of extremities will be saved, many of them it is true with stiff joints, but certainly of better use than artificial limbs. I think it is unnecessary to say that the operation should be performed only by experienced surgeons.

In some of the cases (1, 6 and 8) shortening up to more than 1 inch of the operated extremity took place within the immobilization period.

The extensiveness of the operation, particularly involving muscle and the tendency to postoperative hematomas, which follows the removal of the tourniquet with clot accumulation in the dead spaces, results in a considerable danger of postoperative infection. This occurred in three of the cases, necessitating the amputation of the extremity of one of them; the two

others recovered. I have recently changed the method slightly by implanting the tibial graft in the center of the top of the head of the tibia instead of in front. This prevents the telescoping of the graft along the tibial gutter and it also lessens the difficulty of preventing dead space at the popliteal region. The muscle sleeve can be closed much tighter around the graft and the peril of dead spaces along the graft is diminished. Much painstaking suturing with continuous sutures of muscle tissue about the graft should be done, a curved round point needle being used.

After everything has been said, the most important lesson to be derived from these thirteen cases over a period of seventeen years is that there has been no local recurrence of the tumor. From this point of view the procedure has proved as safe as amputation. In every case amputation was indicated.

57 West Fifty-Seventh Street.

#### ABSTRACT OF DISCUSSION

DR. ARTHUR STEINDLER, Iowa City: One cannot help being impressed in Dr. Albee's paper by the brilliance of his technic. He demonstrates the possibility of substituting by osteoplastic methods for these great defects that arise from radical resection. In a certain percentage of cases of Paget's disease, malignant degeneration occurs. It is noted that in most of these operations the shelling out of the tumor is surprisingly clean and easy. I take it that these tumors were comparatively of a mild degree of malignancy and certainly in the stage before a wide proliferation in the tissues has taken place. My experiences with bone graft replacement in bone tumors are confined exclusively to giant cell tumors and giant cell sarcomas. Everybody knows the difficulties of histologic differentiation between the two types. In addition to this there is the relation of benign bone cyst to giant cell tumor, which is considered a variant of the former by Geschickter. A giant cell tumor at the lower right femur was thoroughly curetted, and the defect, bigger than a man's fist, filled with bone chips, removed from both tibias, which were tightly packed. This tumor consisted of a dense accumulation of giant cells which filled the active center of the tumor, though at the endosteal side of the periphery it was more fibrous and showed a tendency to formation of partially calcified fibrous bone. The roentgenogram showed that most of the implanted bone chips had taken, but the amount was too small to fill the huge cavity. I have seen small cysts completely filled out after curetting and filling in with bone chips. On the other hand, the one experience that I had with a giant cell tumor was instructive. The tumor was in the neck of the femur, where it formed a huge cyst, covered by a paper-thin shell of bone, perforated in places but without infiltration of the soft tissues. The cyst was filled with bloody fluid, probably from recent infarctions, and lined with a wall of granulated tumor tissue. The impression was that of a giant cell tumor with cystic degeneration. The cavity was curetted and filled with a mass of bone chips. The patient did not get well after operation and developed a generalized adenopathy but no metastatic lesion. The roentgenogram showed an extension of the process, and an exploratory operation revealed the upper third of the femur practically gone, the big, blood-filled cavity lined with an irregular wall of tumor tissue, and extensive infiltration of the surrounding soft tissue. The histologic examination now showed a highly malignant giant cell sarcoma. Malignant degeneration of benign bone cyst is reported as a rarity. This singular experience seems to indicate that, gratifying as the results of graft or bone chip replacement may be in cyst or benign giant cell tumors, they are not encouraging in malignant giant cell sarcoma. I mention this merely in relation to the fact that Dr. Albee believes in and has emphasized the radical removal of giant cell tumor because of its potential degeneration, because he thinks that the results of curettement and the filling in of the bone are unsatisfactory. It might well be that this is the case, and this particular experience which I have cited seems to bear out this fact.

#### AIR-BORNE INFECTION

WILLIAM FIRTH WELLS, B.S.  
AND  
MILDRED WEEKS WELLS, M.D.  
CAMBRIDGE, MASS.

In the dissemination of plant life, the atmosphere is nature's prime sower of the seed and thus vitally affects all living things. Air currents, by gripping the extended surfaces of winged larger seeds and the protuberances of the smaller pollens, lift, transport and release them at their destinations. As the size of particles decreases, the weight decreases more rapidly than the surface area and the tiny spores of molds and fungi require no special adaptation for air travel. Bacteria are even smaller, but since they have no power to invade the atmosphere except in association with other matter, their flight range is determined not by size but by the character of the matter with which they are associated.

"Dust and droplets wafted into the air include bacteria. The number of such temporary passengers on the wing depends upon the kind, the source and conditions which lift them into the air, their survival rate, the air currents which transport, disperse and dilute them within the atmosphere, the rate of deposition and the physical and chemical conditions of their atmospheric environment."<sup>1</sup>

The theater of operation of these phenomena is vast: micro-organisms have been found in polar flights and in the highest penetrations of the stratosphere. We are not concerned with this outer atmosphere except as a source of infinite dilution, and in this paper only the dense layer close to the earth's surface will be considered. Particularly in those semienlosed atmospheres wherein we live, dilution is restricted and the spread of parasites is facilitated. On the other hand, these ventilated spaces are also most subject to human control.

Perhaps a discussion of bacteria in air should begin with the pregnant researches of Louis Pasteur, which inaugurated the science of bacteriology and the germ theory of disease. His classic experiments on spontaneous generation, published in 1861,<sup>2</sup> proved that air was populated with microscopic germs which caused putrefaction and fermentation. This fact seemed to substantiate the universal belief that air was the vehicle of contagion, and for twenty years thereafter this thought motivated the work of Lister<sup>3</sup> and of Tyndall.<sup>4</sup> Strangely enough, the perfection of bacteriologic technic during the last two decades of the nineteenth century, in which the specific agents of disease were identified, disclosed in rapid succession their transmission by other routes without demonstrating in air recognized pathogenic organisms. When Flüge<sup>5</sup> failed

to recover nasopharyngeal organisms on plates exposed farther than a few feet from a person's coughing and sneezing and concluded that they settled out in short distances and in brief time intervals, air-borne infection seemed almost eliminated. Meanwhile, sanitary bacteriology during the next twenty years, by demonstrating general bacterial contamination, seemed to justify the belief that such diseases as could not otherwise be accounted for were spread by direct or indirect contact. In the face of the growing momentum of contrary opinion based on this negative evidence, the case against air was dismissed with a Scotch verdict, and the theory of air-borne transmission of infection was well-nigh abandoned.

During the past five years, certain developments in the technic of air bacteriology at Harvard University have caused a modification of our views regarding the inability of air to transmit infection. The invention of an instrument<sup>6</sup> for the extensive exploration of and the practical experimentation on controlled atmospheres initiated these studies. The development of a technic for producing bacterial suspensions by atomizing cultures into these controlled atmospheres became an important factor in the experimental investigation. The technic so developed provided a means for the study of the dispersion of bacteria in air, and the effect of physical and chemical agents on their viability.

THE EXCHANGE OF NASOPHARYNGEAL FLORA  
BY AIR

*Droplets and Droplet Nuclei.*<sup>7</sup>—Droplets expelled into the air from the nose and throat in sneezing, coughing, and the like, do not necessarily, as was concluded from Flügge's experiments, fall immediately to the ground within a short distance from their source. This theory is based on an assumption of constant size, which ignores the important factor of evaporation. As droplets become smaller, the surface exposed to air resistance becomes relatively greater when compared to the weight or gravitational pull toward the earth, and droplets therefore, in accordance with Stokes's law, fall more and more slowly as the size becomes smaller and smaller. The rate of evaporation, which also depends on the surface area, becomes relatively more rapid as the droplet volume becomes smaller, and some size must exist smaller than which a droplet could not fall the height of a man without complete evaporation. This droplet size has been estimated as approximately 0.1 mm. The residues of droplets of this size, derived from physiologic solution of sodium chloride or from body fluids are, after evaporation, so small that their behavior in air is more comparable to a particle of smoke than to the droplets described by Flügge. They may be considered to float or drift with the slightest air currents and therefore to be in effect a part of the atmosphere itself.

This fact may be simply demonstrated by atomizing liquids into a dark enclosed chamber, such as our experimental tank, through which a strong beam of light is projected. Distilled water evaporates almost immediately, leaving no evidence in the beam. If the liquid contains substances in solution, the nuclear residues leave a fog on evaporation, which is clearly revealed by the Tyndall effect. The presence of salts

suspended in air can be easily demonstrated by drawing the air through a Bunsen flame.

Liquid suspensions of micro-organisms may be atomized into the tank and their presence can be easily demonstrated quantitatively by the air centrifuge. It may readily be shown that they persist in diminishing numbers for hours or days.

Transmission of infection through the air may therefore take one of two forms, depending on the size of the infected droplet. The more obvious form, recognized by Flügge, is droplet infection proper. It applies to droplets larger than 0.1 mm. in diameter, which are rapidly removed from the air by gravity before they can dry and within a short distance from the source.

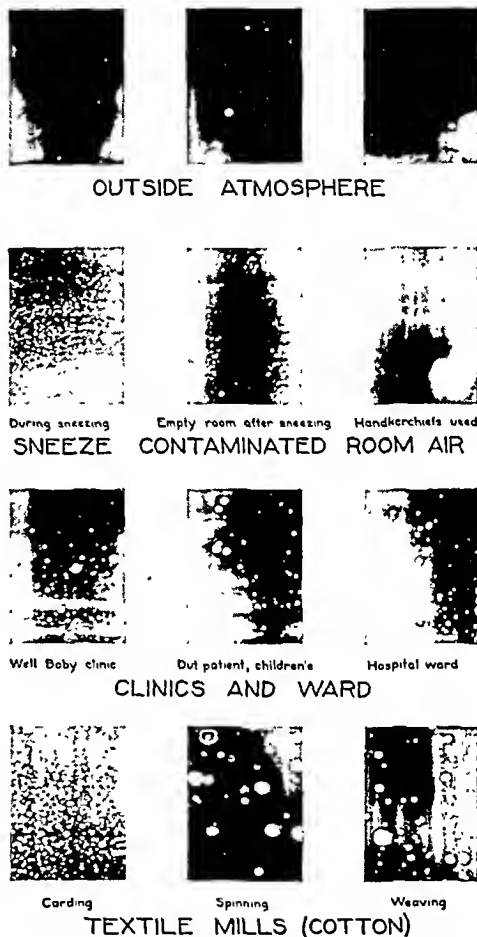

Fig. 1.—Bacteria in air.

The second form may be called air-borne infection and deals with the dried residues of infected droplets, or droplet nuclei, derived directly from droplets less than 0.1 mm. in diameter, depending primarily on air for the buoyancy that keeps them suspended for longer times and carries them longer distances. Droplet infection may change into air-borne infection when larger drops settle, evaporate and are lifted into the air as dust.

The epidemiologic characteristics of droplet infection and droplet nuclei infection are by nature opposite. Droplet infection is essentially localized and concentrated, while infection broadcast by droplet nuclei is more dispersed and dilute.

The basic fact that micro-organisms can remain suspended alive in air for periods which may permit their wide dissemination has thus been demonstrated.

7. Wells, W. F.: On Air-Borne Infection: II. Droplets and Droplet Nuclei, *Am. J. Hyg.* 20: 611 (Nov.) 1934.

*Viability of Droplet Nuclei Infection.*<sup>8</sup>—The interval of time spent in the air by Flügge droplets is too brief for significant change in the viability of infection, as it is also too brief for wide dissemination. Since droplet nuclei remain in suspension for long times and may drift considerable distances, the viability of the bacteria associated with them becomes an important factor in the spread of air-borne infection. The difference between the rate at which droplet nuclei are removed from the atmosphere by settling, and the rate at which infection disappears from the air into which they are expelled, depends on the rate of survival of micro-organisms attached to these nuclei. The disappearance rates have been determined for sixteen organisms, chosen to represent several different normal habitats and other characteristics of hygienic significance in the problem of air-borne infection.

The disappearance of the Pfeiffer bacillus within an hour was in sharp contrast with the long period of several days that *B. subtilis* persisted in the air of the chamber. *Staphylococcus aureus* disappeared more rapidly than *B. subtilis*, but since it was recovered after three days it may be classed among the more resistant organisms. The water-borne organisms, on the other hand, *B. prodigiosus*, *B. pyocyaneus* and *B. violaceus*, did not survive one day, how much less a time being undetermined.

Four organisms characteristic of the respiratory tract, pneumococcus type I, *B. diphtheriae*, *Streptococcus haemolyticus* and *Streptococcus viridans*, were recovered after two days, while none of the four organisms typical of the intestinal tract, *B. coli*, *B. dysenteriae* Hiss Y, *B. typhosus* and *B. paratyphosus* A, were recovered at the end of the first day or at the end of eight hours when samples were taken after this time interval. If the Pfeiffer bacillus may be excepted as a special case, this respiratory group of organisms may be regarded as decidedly more viable in air than the intestinal group of bacteria, in spite of the rapid decrease in both groups.

Bacteriophage active against the Hiss Y dysentery bacillus was recovered from air at the end of twenty-four hours and cultivations from the plaques demonstrated the identity of the bacteriophage. The rate of disappearance during the first three hours also resembles the behavior of bacteria in air. The viability of this bacteriophage was therefore greater than for the intestinal group and less than for the respiratory group of organisms.

The recovery of virus experimentally suspended in air was made possible through the collaboration of Dr. H. W. Brown, who had previously become proficient in the identification of the virus of influenza. The lungs of a ferret infected with the Puerto Rico 8 strain<sup>9</sup> of influenza virus being used as the source of infection, filtered liquid suspensions of virus were atomized into the tank, recovered in liquids by the air centrifuge, and inoculated intranasally into ferrets.<sup>10</sup> All the ferrets inoculated with the material collected from the air within an hour after suspension contracted influenza. None of the ferrets inoculated with samples collected from the tank an hour or more after suspension of the virus contracted the disease. On the basis of this exploratory study, in which the technic was evolved as

it progressed, it is not believed that the viability end point of influenza virus has necessarily been reached.<sup>11</sup>

The time and distance which infection from droplet nuclei may travel depends more on the viability of the organisms in air than on the settling rate. The differences in viability of the various micro-organisms when suspended in air seem to be significant.

*Dust and Droplet Nuclei.*—The slow rate of settling of nuclei produced by evaporating droplets distinguishes them from particles of bacteria-laden dust. It should be obvious that the number of particles that settle on a given area in a given time depends not only on the number of particles in the air but also on the rate at which they settle. Since the coarser particles settle more rapidly, more larger particles would settle on a given area in a given time than smaller particles assuming equal concentrations in the air, as determined by the centrifuge. The ratio between the plate count and the number in a given volume as determined by the centrifuge may thus be used to indicate the rate of settling and the equivalent size of suspended particles.

It has been found by tests on artificial humidification with bacteria-laden water that the nuclei of the evaporating droplets settle with extreme slowness as compared with the settling rate of ordinary atmospheric dust. A hundred times as many dust particles as nuclei settle on a plate for the same atmospheric concentration. Twelve out of fifteen eosin methylene blue plates remained sterile when exposed for fifteen minutes to air containing 250 *B. coli* in each standard sample of 10 cubic feet, as determined by the centrifuge. This shows the impracticability of Flügge's technic for determining the presence of micro-organisms in nuclei resulting from mouth spray. His tests showed that they remain suspended in the air rather than that they settle out in a short distance. With the centrifuge, however, they may be readily demonstrated.

These conclusions were corroborated under practical working conditions in a study of the bacterial contamination of the air of textile mills in Massachusetts.<sup>12</sup> Much dust is lifted into the air of the breaking and carding rooms in cotton mills. Comparatively small amounts of dust are found in weaving rooms, but enormous quantities of water are required to humidify the air. The ratios of plate to tube counts in the dusty rooms was four times greater than the ratio in weaving rooms, which were heavily humidified, showing the high preponderance of dust in the former and of nuclei in the latter.

Little doubt can remain as to the adaptability of nuclei to be conveyed by air when it is found that they drift with so much greater readiness than the dust with which all are familiar.

*Dispersion of Droplet Nuclei Through Buildings.*—Wide distribution of "nuclei" in a building was demonstrated by inoculating with a culture of *B. coli* the humidifying water of a one-room air conditioner in the basement of the Harvard School of Public Health. This building does not have mechanical ventilation and it conforms in general design to the building of the National Institute of Health described by McCoy<sup>13</sup> in which psittacosis virus appeared to have been conveyed

by air from the basement to upper floors. Numbers of *B. coli* were recovered from the ends of every corridor up to the top floor of the three-story building, where the concentration reached approximately 1 per cent of that in the air-conditioned room.

Infected nuclei can therefore be dispersed by ventilating currents throughout a building, as was shown by the dispersion of nuclei from humidification with contaminated water.

*Expulsion of Droplet Nuclei by Sneezing.*—These air-floating nuclei are peculiarly adapted to bear infected matter, and the physiologic processes of respiration provide an obvious mechanism for implantation on the nasopharyngeal tissue of a person breathing the air. There remains in the chain of evidence of air-borne infection the demonstration that droplets sufficiently small to evaporate completely are actually expelled into the air by expiratory processes and that such droplets may, during pathologic reactions, be infected.

The experimental demonstration that large numbers of nuclei, infected by organisms typical of the nasopharynx, are expelled in sneezing, forged the last link in this chain of evidence. By the simple procedure of broadcasting small amounts of "sneeze powder" into a room, a practical joke was turned into a conclusive experiment. Fifty sneezes were induced from a group of subjects in a standard air-conditioned room. Bacterial samples collected in the air centrifuge on blood agar tubes revealed thousands of alpha streptococci and *M. catarrhalis*. Even after the subjects had left the room, the air contained many hundreds per sample. The application of handkerchiefs to smother the sneeze showed marked results in preventing expulsion of micro-organisms into the atmosphere. These results are illustrated in figure 1.

A convincing experiment was conducted under natural conditions in a demonstration of the air centrifuge to a class of twenty-five graduate students in a room of about 10,000 cubic feet capacity. The air centrifuge was placed at the speaker's table at least 10 feet away from the nearest person and the exhaust pointed not toward the class but laterally. The air centrifuge inspires continuously at about the same rate as a person during the maximum phase of inspiration and may therefore be considered a mechanical subject. A small amount of "sneeze powder" was dusted into the exhaust stream of the air centrifuge, being thereby projected into the room more as in normal expiration than in the more violent act of sneezing. That the expired air carried the particles to the class after a lapse of several minutes was indicated by occasional sneezes during the next ten minutes. Sneezing had ceased before the second ten-minute tube was taken, following which the class was dismissed and a third sample taken. The first tube, taken during the interval of sneezing, showed, on incubation, many alpha streptococci. The second tube, taken after the sneezing had ceased, however, showed a very large increase, thus indicating that the organisms had become dispersed throughout the room and were returning to the machine. The third tube showed a marked decrease but still gave positive evidence of contamination. In this experiment, contamination of the air by the machine was evidenced by the sneezing, and contamination of the room by the sneezers was evidenced by bacterial colonies in the tubes. A perfect cycle was thus completed and little doubt can possibly be entertained that most of the persons in the room were infected by the machine and by one another.

Whenever a person sneezes, many thousand nasopharyngeal organisms remain suspended in the air, and in commonly occupied, enclosed spaces, the exchange of nasopharyngeal flora is inevitable.

*Recovery of Nasopharyngeal Organisms in Normal Occupied Atmospheres.*—It is not necessary to employ experimental expedients to demonstrate the exchange of nasopharyngeal flora in occupied spaces. A little skill in the recognition of alpha streptococci on blood agar tubes makes their normal recovery during the winter a simple routine performance.<sup>14</sup> Samples of air taken from well baby clinics, children's medical clinics, hospital wards, theaters, factories, school rooms and outdoor air confirms the deduction that the numbers of alpha streptococci correspond to the degree of contamination by the occupants, as shown in table 1. It would seem obvious that under conditions of crowding in enclosed rooms we are breathing one another's nasopharyngeal flora as we once drank each other's intestinal flora in our water supplies, and the consequences of such practices become a study in sanitary science.

We wish to resuggest<sup>15</sup> the alpha streptococcus, an organism normally present in the nasopharynx, for similar service in indicating the degree of nasopharyngeal contamination of air, to that of *B. coli* in drinking water as indicating the degree of intestinal contamination, since the implied potentialities are analogous. An extensive study of the great diversity of inhabited atmospheres of New York City has been conducted during the past winter, and the results of 2,000 samples bear out this conclusion.

The sanitary analysis of air of normally occupied rooms establishes the nasopharyngeal contamination of our breathing air, as the presence of *B. coli* establishes the presence of intestinal contamination in drinking water.

#### AIR-BORNE INFECTION AND AIR-BORNE DISEASE

*Universality of Nasopharyngeal Infection.*—These bacteriologic experiments would seem to demonstrate a mechanism of air-borne infection that provides for the exchange of nasopharyngeal flora. The burden of proof of air-borne infection, which had hitherto rested on bacteriology, has been lifted, and there now rests on epidemiology the burden of disproof of air-borne disease. Except in the case of such manifestly widespread clinical diseases as measles and smallpox (uncomplicated by vaccination), in which intensive outbreaks seemed almost to require the possibility of air-borne transmission, such disproof did not seem difficult a quarter of a century ago.

It has seemed almost axiomatic that contamination of the air we breathe should bring about almost universal infection, although contamination of a common water supply does not necessarily do so. The quantitative factor of dilution could account for the occurrence of sporadic cases of air-borne respiratory infection, just as it accounts for sporadic cases of water-borne intestinal disease.

Nevertheless the widespread occurrence of clinical cases of measles and smallpox (in which infection is manifested by disease) almost requires the hypothesis of air-borne transmission. At the time when the indictment against air was dismissed, the extent of spread of infection was defined by the extent of the spread

of clinical disease, in this definition the two being synonymous. While carriers had already been recognized and been assigned an important rôle as infectors in the spread of disease by contact, their rôle as infectees in the epidemiologic determination of the extent of spread of infection was disregarded. Means for tracing subclinical infection have since revolutionized the concept of the extent of spread of infection<sup>16</sup> through the nasopharynx, though much of this evidence has not yet been assimilated into our epidemiologic thought. The mass of evidence accumulated by tests for immunity and sensitiveness, for carriers, and for epidemiologic studies of age incidence, now indicates that many, if not most, of these infections spread as readily and as broadly as the virus of measles. lated into infections, these tests may be interpreted as evidence that few children escape the nasopharyngeal infections, and probably most adults have been infected and repeatedly reinfected.

Where the clinical cases of these diseases represent only a small fraction of the infections, conclusions based on cases must be revised before being offered in evidence. It has been argued<sup>17</sup> that in the enclosed atmospheres of contagious hospitals, with known cases of nasopharyngeal disease, the incidence of secondary cases was too low to warrant the conclusion that the air of the building, shared by all, was infective. The factors of immunity, of subclinical infections and of preclinical infectiousness have been overlooked in the interpretation of the much quoted reports on hospital cross infection. When were the cases most infective, before or after coming to the hospital? Of the exposed, how many were already immune, what was the nonimmune

population actually at risk per annum? How many were infected but reacted with an immunity response rather than the clinical disease? How much seed fell on stony ground?

The cases of "diseases of childhood," the total number of infections required to immunize a population to these diseases before maturity, and the repeated attacks of those diseases in which no permanent immunity is conferred reveal a universality of infection which falsifies the premises on which was based the conclusion that the air, breathed by all, cannot be infective.

If the total number of nasopharyngeal infections required to immunize a population before maturity is compared with the number of intestinal infections that would condemn a water supply as being highly dangerous, it might be concluded on epidemiologic grounds that the atmospheres of our common habitations are even more highly infective. It may be that the air of our schools, institutions and homes, where children mix freely in the highly infectious preclinical stage of disease, where many more harbor infection subclinically, where air is less diluted than in separate wards opening into common corridors, or even in wards where bed isolation is practiced, is more heavily infected than the air of contagious hospitals.

The universality of nasopharyngeal infection does not prove that it is air borne, but it meets the objection that, if air were infective, nasopharyngeal disease would be universal.

**Velocity of Spread.**—The aptness of the theory of air-borne infection to account for disease transmission has never been questioned, and "the theory is reluctantly given up, since it is the easiest method of explaining the spread of readily communicable diseases."<sup>1</sup> Those, however, who have adopted the alternative theory of "contact" infection will point out the undeniable fact that the special conditions which have been set up for the spread of air-borne infection are likewise conducive to intimate contact. Just what is meant by the word contact as applying to the spread of infection should be defined in objective terms before the two theories can be contrasted.

If the more or less direct spread of infection from person to person, the quick transfer of fresh infective material, proximity in time and space between infected and noninfected, constitutes contact, then the condition of air-borne infection by breathing one another's air in semienclosed spaces would constitute a rather extended form of contact infection. The preceding discussion has not assumed the broadcasting of infection in the sense that wind-blown pollens causing hay fever are broadcast.

While these distinctions may reconcile those to whom the words "air-borne infection" might revive the ancient and exploded theory of miasms, failure to extend the concept of "contact" may lead to the breakdown of measures for the prevention of this type of infection. It is necessary therefore to distinguish the different phases of "contact," and it would seem that this might become possible by a statistical examination of the velocity of spread by the different phases.

If contact infection requires that an uninfected person touch an infected person in some particular manner, or touch something in a particular manner which the infected person has touched in a particular manner, or that the two be within the short radius of Flügge droplets during the brief interval of fall, the rate of spread would be limited by these circumstances. If the

chance of infecting each individual is not large, the chance of simultaneous infection of many would be exceedingly small, and disease would limp in its spread. (Contact outbreaks of typhoid die out not from exhaustion of inflammable material but from difficulty of transferring the spark.) If, on the contrary, the sneeze-infected air of a room were breathed by many persons over a considerable interval of time, simultaneous infection could be realized, and the velocity of infection would be ample to explain even the explosive pandemic of influenza in 1918-1919. If refinements in statistical methods can determine the velocity of subclinical infection, it may be possible to distinguish between these two modes of transmission.

Recognizing, of course, that all forms of contact work cooperatively in spreading infection, there is good reason to believe that only that phase which is called air-borne infection can be swift enough to explain the epidemic spread of nasopharyngeal disease in non-immune populations.

*Diseases as Biologic Entities.*—If infectious disease may be regarded as a biologic entity requiring the continuous propagation of parasites through a chain of hosts,<sup>18</sup> it would follow that a mode of transmission on which the continuity of the disease depended must postulate a means for the parasite to leave its discarded host, exist, and be transported to a new host into which it must gain entrance. The characteristics of diseases conveyed through the nasopharynx would seem to satisfy such postulates, as their pathology provides for a means of infecting air, the etiology seems to indicate causative agents capable of existing in air, and physiology provides for the planting of the parasite on the respiratory passages of a new host. Their universality even at early ages indicates widespread infection clinically or subclinically, and the velocity of spread seems to be characteristically explosive.

If one compares diseases as a group whose portal of entry and exit is the nasopharynx with those whose entrance is through other portals, one finds marked group contrasts. The nasopharyngeal group may in these respects be contrasted with typical gastro-intestinal diseases; where frequent uncontrolled liquid discharges are conducive to the contamination of food, milk and water; where the organisms can readily survive, if not multiply, in these mediums and appear unadapted to life in air; where the epidemiology makes it possible to incriminate such sources even though the organism cannot be found, and where control measures have dramatically demonstrated the soundness of the hypothesis.

They may be contrasted with the insect-borne diseases where discharge of the organism is not pathologically provided; where the organism cannot survive the rigors of environmental transfer, but the existence of which in the peripheral circulation adapts them to withdrawal through the proboscis of an insect, within whose body they are adapted to survive or even of necessity bound to sojourn; where the occurrence of the disease is perfectly circumscribed by the prevalence of the insect, and where control of insects inevitably stamps out the disease.

They may be contrasted with typical contact diseases such as the venereal diseases, where external lesions are habitually brought into physical contact with susceptible tissue; where life of the pathogen outside the body is almost impossible; where any other explanation of

transmission is regarded with skepticism, if not derision, by the specialist, and where prevention is limited by the power to control the contacts.

The argument that once all communicable diseases were attributed to air and that, the more perfect becomes our knowledge, the less air becomes implicated cannot in view of these differences be carried *ad absurdum*.

The more intimate our knowledge of the modes of transmission becomes, the more evident does it become that diseases are adapted to transmission by diverse routes, and among these air transmission of nasopharyngeal infection may not be the least important.

*Nasopharyngeal Infection Still Uncontrolled.*—Where the transmission of disease has been prevented by control measures, there can be little doubt as to the correctness of the theory of transmission. It may therefore be significant that those diseases which have so far defied control are those in which the causative agent enters and leaves through the nasopharynx. In an evaluation of the importance of diseases made by the United States Public Health Service,<sup>19</sup> the only infectious diseases considered as of a first order of magnitude were influenza and pneumonia, and tuberculosis.

The Public Health Service figures show, in particular, that:

1. More than 85 per cent of the deaths from infectious and parasitic diseases occurring in the United States in 1933 were from diseases in which the usual portal of entry of the causative micro-organism is the nasopharynx.
2. Of the important reportable diseases in 1933, the incidence of measles was highest, that of influenza second.
3. Of the incidence of illness, based on nation-wide periodic surveys in 1928-1931, colds and bronchitis, influenza and pneumonia, and tonsillitis occupy the first three places in annual incidence, causing considerably more than half of the total cases.
4. Among industrial workers during 1933, the largest single cause of illness of eight days' duration was influenza and pneumonia.
5. Nation-wide periodic surveys in 1928-1931 show that influenza and pneumonia caused more days in bed than any other disease. Colds and bronchitis rank second, tuberculosis third. The diseases spread through the nasopharynx caused a total of 218 days in bed for every 100 persons, as against 167 days in bed from all other causes combined.

The predominance among infectious diseases of those transmitted through the nasopharynx challenges public health measures of control. Until the purity of our common air supplies can be established through sanitary control, the transmission of these diseases by air cannot be disproved.

**Acetylcholine.**—The results of the experiments of Dale and Gaddum lacked only the direct proof of the substance produced by nerve stimulation. This proof has been given lately by Kibjakow for the antidromic fibers and by Feldberg for the antidromic and the chorda fibers. Both investigators independently found that by stimulation of the respective nerves a substance passes into the circulating fluid which shows a vasodilator effect as well as other properties of acetylcholine.—Loewi, Otto: The Humoral Transmission of Nervous Impulse. The Harvey Lectures, Baltimore, Williams & Wilkins Company, 1934.

HELMAN C. WASSERMANN, M.D.  
ST. LOUIS

In 1915 a symposium on so-called twilight sleep was held before the St. Louis Medical Society. Tilles<sup>1</sup> reported his experience in eleven private cases in which he used scopolamine-narcotine. Gellhorn and Kerwin<sup>2</sup> reported fifteen City Hospital and three private cases, having employed Siegel's modification of Gauss's method. Schwarz<sup>3</sup> presented fifteen cases together with an experimental and clinical study of scopolamine-narcotine seminarcois.

Early in 1919 Dr. Henry Schwarz<sup>4</sup> presented the first thousand cases of delivery in Barnes Hospital. Since this time various other publications from the St. Louis clinics have come out as more cases have been observed. In 1929 there were 4,212 cases reported from Barnes and St. Louis Maternity hospitals, making

a total number of 8,166 deliveries that were analyzed up to Feb. 15, 1929, scopolamine-morphine having been used in 4,113 of the deliveries. Only 7,166 of the foregoing are included in table 1, which shows the distribution of the cases and the fetal mortality.

In 1915, when Gauss's method was being investigated, animal experimentation was carried on in the pharmacologic laboratories of the Washington University School of Medicine to determine the effects of the various opium alkaloids and scopolamine on heart and respiration before the drugs were employed in a routine clinical way.

These experiments showed that scopolamine in doses much larger than were ever recommended for twilight sleep has no material effect on blood pressure or respiration. Also that the interference of the opium alkaloids (morphine, narcotine, and morphine-narcotine

meconate) with the respiration in the new-born child is twofold; first the respiratory center is depressed, and in the second place there is bronchoconstriction.

We have been using scopolamine hydrobromide in ampule form with morphine sulfate in one-sixth grain (0.01 Gm.) doses for the induction of twilight sleep. Various other preparations in tablet form have been tried out but this is most convenient and uniformly active pharmacologically.

We use scopolamine-morphine seminarcois as a first stage measure and begin it when the patient is in active labor, usually determined by an obliterating cervical canal. In the hands of the less experienced it may best be started when the uterine contractions are strong and occur at regular intervals and usually when there is at least two fingers' dilatation in the primiparous patient. In the multiparas, the procedure is usually begun with the first regular contractions that are painful.

The method as first employed has stood the test and has not been found wanting in more than twenty years of its use. The patient undergoes the usual preparation for delivery before the seminarcois is begun. The dosage of the various drugs has remained the same with but minor changes in the hands of various individuals. The initial injection contains morphine one-sixth grain (dilaudid hydrochloride at times), and scopolamine hydrobromide  $\frac{1}{133}$  grain (0.5 mg.), the former never being repeated. The interval of injections has gone unchanged, forty-five minutes elapsing between the first and second and the second and third injections, and from that point on the dosage is determined by the patient's loss of coordination and depth of seminarcois.

When the seminarcois is intensified to general anesthesia by a general anesthetic at the time of delivery, great care must be exercised to prevent the giving of too much anesthetic. Chloroform administered properly in the normal patient is almost ideal. From ten to fifteen drops of chloroform on a thin gauze mask is usually sufficient to render the patient completely relaxed. There is an inclination toward giving too much chloroform, and by so doing the mother is not only chloroformed to a much deeper degree than the occasion demands but the fetus is also chloroformed so deeply that it is bound to be born apneic, to become asphyxiated and to require resuscitation. Ether, nitrous oxide and ethylene are also used at the time of delivery as the case demands.

Morphine seminarcois is most applicable during the first stage of labor, particularly in the primiparous patient or in the multiparous patient in whom previous repair work has been done on the cervix, or in whom the first stage is protracted and painful because of premature rupture of the membranes or a long rigid cervix. In cases of delivery through the natural passages in women who on a previous occasion have been delivered by abdominal cesarean section, it is of the greatest importance to prevent all straining on the part of the parturient woman and to extract the child as soon as dilatation is completed, so as to keep all strain as far as possible from the uterine scar. In cases of pulmonary tuberculosis and in cardiac disease, seminarcois is also successfully used.

We may say here that after the method was employed in the first 150 to 200 cases it was felt that it was a procedure without appreciable danger to mother or child and that it had no marked effect on the prolongation

of labor. In previous papers we<sup>5</sup> have demonstrated the fact that it had a definite tendency to shorten the first stage and slightly lengthen the second stage. In order to meet the criticism that under scopolamine-morphine semimarcosis more forceps deliveries are necessary, we observed a series of thirty-four consecutive primiparas. During this period there were two or three patients delivered instrumentally for definite indications on the part of the mother or child, but such cases will be found in any series regardless of the anesthesia or analgesia employed. We do not feel that there is any particular end to be gained in permitting

with a moderately contracted pelvis. We did not at any time expect to show any brilliant statistical figures to point out the advantages of the method but felt that it was particularly indicated under such special circumstances.

In our previous papers we have stated that there are no disadvantages of the method to either mother or child, although the mother in some instances is somewhat restless during the pain and occasionally somewhat excitable. However, we know of no method which by such a simple procedure as two or three hypodermic injections can result in such complete amnesia over such

<sup>a</sup> Quinetherol contains ether 75 cc., quinine alkaloid 1.3 Gm., alcohol 12 cc., and liquid petrolatum to make 120 cc.

spontaneous delivery; we employ perineal forceps and episiotomy incisions in the primiparas almost as a routine. After we had derived a considerable experience from these cases we felt that it had its greatest usefulness in cases in which labor was likely to be prolonged, particularly in elderly primiparas and in patients

a considerable period that it enables at least 80 to 85 per cent of these patients to go through labor without its recollection. Fetal asphyxia is not increased, although children are occasionally born in a state of oligopnea, from which usually they promptly recover on appropriate stimulation.

S.: Scopolamine-Morphine Semimarcosis: Its Use in the First Thousand Deliveries in the St. Louis Maternity Hospital, read before the St. Louis Medical Society, April 30, 1929. Krebs, O. S.: Scopolamine-Morphine Semimarcosis, *J. Missouri M. A.* 26:485 (Oct.) 1929 (read in the symposium on obstetrics at the 72d Annual Meeting of the Missouri State Medical Association, Springfield, May 13-16, 1929).

The disadvantages are chiefly from the standpoint of the attendants. Some one must be constantly with the patient, particularly the one who is supervising the injections. It may be said that much of our success with the method has been due to the untiring efforts of our house officers during this period of twenty years. They have seen to it that the patients whom they have handled have suffered no unnecessary pain during their labor by the careful supervision of this method. The other disadvantage is the not infrequent restlessness and occasional excitability of the patient. That is,

however, by no means striking. It has no effect on the patient herself but at times is quite taxing to the attendant.

In the last few years, with the increasing popularity of the barbituric acid derivatives, various of these preparations have been used with scopolamine hydrobromide and morphine usually preceding the latter drugs in administration. In many instances the results were so gratifying for several reasons that the use has been extended. In the first place there seems to be less excitability evidenced in the patient, which has been one of the sources of dissatisfaction that we have found occasionally when employing our original technic. Scopolamine hydrobromide has been administered in the primiparas when active labor has begun and when there has been about two fingers' dilatation. We find that we now can keep the patient quite comfortable during the prodromal stages prior to the time we ordinarily start the seminarcosis and that the latter takes hold more quickly in spite of active labor. The latter fact has led us frequently to reduce the amount of morphine or other opiate in our first injection of so-called twilight sleep or even to discontinue its use entirely and has also improved the amnesia in multiparas advanced in labor on entering the hospital. The omission of the opium alkaloids, which drugs Jackson in 1915 held as likely to interfere with the prompt establishment of respiration in the new-born child, has had a definite result in the lessened number of apneic babies born. A separate

bromide and other drugs. Scopolamine hydrobromide was used in 1,427 deliveries. Although scopolamine hydrobromide was used in 350 more cases in the second series, it was used with opiates 154 more times, which shows not a decreasing use of scopolamine-morphine for other drug combinations but rather an extension of the use of scopolamine hydrobromide with other drugs, owing to its wider applicability. This additional use of scopolamine hydrobromide was in the primiparas, generally speaking. There was a total of 1,072 and 551 multiparas in the first and second groups, respectively, and the incidence of scopolamine hydrobromide was 436 (41 per cent) and 286 (51 per cent), respectively. At the same time, the frequency of primiparas was 928 and 1,449 in the first and second groups, respectively, with the employment of scopolamine hydrobromide in 641 (69 per cent) and 1,141 (79 per cent), respectively.

The corrected mortality figures in the first 2,000 cases in infants weighing 2,500 Gm. or over at birth and excluding macerated fetuses was 2.3 per cent with scopolamine-morphine and 2.4 per cent without scopolamine-morphine, and there was no mortality in 126 cases in which scopolamine hydrobromide was used in combination with other drugs, not including opiates.

In the second group of 2,000 deliveries the corrected mortality with scopolamine-morphine was 1.3 per cent, without scopolamine-morphine 2.8 per cent, and 0.3 per cent in which scopolamine hydrobromide was used with other drugs, not including opiates.

report on this feature in a series of 1,000 cases is being prepared by Dr. Wulff for publication at this time.

To show the increasing incidence of the use of these barbiturates, we have analyzed the first 2,000 cases since our last report in 1929 and also the most recent 2,000 deliveries up to Jan. 1, 1936. There remain approximately 6,000 deliveries between these two groups that have not been studied.

In this first series of 2,000 cases there were 951 deliveries in which scopolamine hydrobromide and opiates were employed, 923 instances in which scopolamine hydrobromide was not used, and 126 cases in which there was a combination of scopolamine hydrobromide and other drugs. Scopolamine hydrobromide was used either with or without opiates 1,027 times.

In the second group of 2,000 cases there were 1,105 deliveries in which scopolamine hydrobromide and opiates were employed, 573 instances in which scopolamine hydrobromide was not used and 322 cases in which there was a combination of scopolamine hydro-

In the combined series of 4,000 cases, the corrected mortality without scopolamine hydrobromide was 2.5 per cent, with scopolamine hydrobromide and opiates 1.8 per cent, scopolamine hydrobromide with all drugs 1.5 per cent and scopolamine hydrobromide with barbiturates 0.3 per cent.

Table 3 shows the distribution of the patients and the fetal mortality in collective groups in which scopolamine hydrobromide was used with opiates and with the barbiturates.

#### CONCLUSIONS

1. The methods for the conduct of labor as we use them can be carried out only by trained obstetricians in a maternity of moderate size. The same general conduct of seminarcosis in labor has been employed for twenty years with satisfactory results.

2. Scopolamine-morphine seminarcosis has found increased employment in the last cases reported, together with an increasing application of scopolamine hydrobromide with barbiturates.

3. From analysis of the records, we feel definitely that scopolamine-morphine seminarcois is in no way increasing fetal mortality.

4. With the addition of barbituric acid derivatives to our original method of seminarcois, the use has been extended.

5. It seems that an almost ideal method is possible in our hands in the use of barbiturates with scopolamine hydrobromide alone or with a reduced dosage of opiate.

6. The method should not be used to the exclusion of other methods of analgesia and anesthesia but should be used in combination with them.

## PENTOBARBITAL-SODIUM AND SCOPOLAMINE HYDROBROMIDE

THREE YEARS' EXPERIENCE WITH THESE DRUGS  
IN OBSTETRICS AT THE EVANSTON HOSPITAL

CHARLES EDWIN GALLOWAY, M.D.

ROBERT M. GRIER, M.D.

AND

ROBERT BLESSING, M.D.

EVANSTON, ILL.

We began using pentobarbital-sodium and scopolamine hydrobromide for the relief of pain in labor at the Evanston Hospital in December 1932. Dr. Frederick C. Irving at the Boston Lying-in Hospital had been using these drugs for some time and with such satisfactory results that we were convinced of their superiority. One of us visited Dr. Irving in December 1932 and received from him and his colleagues all the information then available on the procedure of administering the drugs.

In February, 1935 one of us, with Dr. Philip H. Smith,<sup>1</sup> published a report based on the study of 500 deliveries in which pentobarbital-sodium and scopolamine hydrobromide had been used. At that time we came to the conclusion that our results with this method of pain relief in labor had been sufficiently satisfactory to warrant its further use.

We have now used these drugs almost exclusively for three and one-half years in cases in which we wished to furnish relief of pain otherwise than with gas. We present here a report on the fetal mortality, the maternal mortality and morbidity, and the reaction of the patients based on letters received from a questionnaire. The records of the past three years during which pentobarbital-sodium and scopolamine hydrobromide were being used will be compared with the three years just preceding.

During the three year period that ended Nov. 1, 1935, we delivered 2,275 mothers and the drugs were administered in 1,415 cases, or 62 per cent. One can readily see that these drugs are not used as a routine. We have, however, used almost no other drugs for the relief of pain. If a patient reaches the ward in rapid labor, gas is used both for analgesia and for anesthesia, and nitrous oxide for the former and ethylene for the latter. The other contraindications for the use of pentobarbital-sodium and scopolamine hydrobromide are (1) full stomach. (2) infection of the upper

respiratory tract, (3) prematurity and (4) heart disease. The contraindications, however, have not been strictly followed, as can be easily seen from the content of some of the case reports.

When the patient is in labor, regardless of the amount of dilatation of the cervix, she is given 7½ grains (0.5 Gm.) of pentobarbital-sodium in five separate capsules with a pin hole in each. The earlier it is administered the better. One must be satisfied, however, that one is dealing with true labor. The drug is not given in one capsule because we have found that it was not so effective, a fairly insoluble mass being formed at times when in contact with the hydrochloric acid of the stomach. About five minutes later the patient is given half a drachm (2 Gm.) of sodium bicarbonate in water to help alkalize the stomach. When the pentobarbital-sodium is given, scopolamine hydrobromide, ⅓<sub>150</sub> grain (0.0004 Gm.), is administered by hypodermic injection. Some patients who are smaller than average receive only 6 grains (0.4 Gm.) of pentobarbital-sodium. The initial dose, however, should be large, for one is administering an anesthetic and the patient must pass quickly through the excitement stage and then be kept there by an additional 1½ grain (0.1 Gm.) capsule every two to three hours. This additional amount is necessary because the drug is constantly oxidized in the body. The initial dose for large women is 9 grains (0.6 Gm.). We pay little attention to the ordinary restlessness that comes with the pain except to prevent injury. The labor bed must be extra large, with crib sides covered with padding. Nurses are instructed to handle the patient as little as possible. Every patient has a special nurse assigned as soon as the pentobarbital-sodium and scopolamine hydrobromide are given and the nurse must not leave the bedside until about five hours after delivery.

If the patient becomes restless not only with the pain but also between pains and if her restlessness seems extreme, a little more pentobarbital-sodium may be administered, but never over 3 grains (0.2 Gm.) additional. Then, if she is still restless, no other drugs are administered. Morphine and other narcotics should almost never be administered to such patients until after the third stage of labor. Such cases should be recognized early as failures from the standpoint of anesthesia; nature should be allowed to take its course, and the actions and cries of the patient should be disregarded. The uterus will eventually empty itself. Grave mistakes are sometimes made by going from one course of procedure to another in an attempt to relieve pain. A few examples are shown in the reports covering obstetric fetal mortality. Relief of pain in obstetrics is only one small part of the proper conduct of such cases. A simple effective method should be tried when indicated but abandoned when it fails.

There has recently been published a method of pain relief in labor in which five different drugs are given to the patient within a few hours, by mouth, by hypodermic and by rectum, combining narcotics, a hypnotic and a uterine stimulant. Then, during delivery, gas is used. Such polypharmacy for the relief of pain in obstetrics seems unnecessary and unreasonable.

In a few cases we have repeated the scopolamine hydrobromide after from four to six hours with very good effects. We have not used rectal instillation of ether except in a few early cases, deeming it unwise to proceed too far with too many drugs.

When the patient is ready for delivery she is given ethylene, put to sleep, prepared, draped and delivered.

<sup>1</sup> Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

1. Galloway, C. E., and Smith, P. H.: Study of Nembutal (Pentobarbital-Sodium) and Scopolamine for Relief of Pain in 500 Deliveries, *Am. J. Obst. & Gynec.* 29: 207-215 (Feb.) 1935.

Outlet forceps and episiotomy is the choice procedure for delivery, 20 per cent being spontaneous, with the usual small number of breech and other operations.

If after the patient reaches her bed she is restless in coming out of the gas, she may be given one-sixth grain (0.01 Gm.) of morphine hypodermically and generally with good results. During this period especially, the patient should be kept warm and fluids and nourishment should be provided. She is generally able to drink long

before complete consciousness is reached and should be persuaded to do so. A few patients become rather spastic and respirations become shallow. We have used coramin in such cases and one-sixth grain of morphine hypodermically with very good results. We now have picrotoxin to counteract the effects of barbiturate poisoning but we are not in a position to report on its use. There have been a few cases in which spasticity and shallow respirations have occurred during labor and here too we have deemed it wise to make the exception and have used a small dose of morphine with coramin, with good results.

Table 1 shows the operative incidence compared with maternal and fetal mortality. The increase in the use of outlet forceps and episiotomy has evidently not influenced either maternal or fetal mortality.

The following is a short account of the only maternal death that has occurred during the three year period covered in this study, a rate of 0.07 per cent in a series of 1,415 deliveries for which pentobarbital-sodium was given:

Mrs. L., a primipara, aged 36, was in labor thirty hours with no progress; 10½ grains (0.7 Gm.) of pentobarbital-sodium had been administered sixteen hours previously. Low cervical cesarean section was done, with severe hemorrhage four hours later. Death occurred shortly afterward.

One of the much used generalizations regarding anesthetics in obstetrics is that they will increase morbidity. Table 2 compares the morbidity rate of the group in which pentobarbital-sodium and scopolamine-hydrobromide were administered, with the rate of the group delivered without these drugs over the last three-year period. In all the following figures on morbidity the standard of the American College of Surgeons was used and includes only febrile morbidity.

Table 3 shows a comparison of the two three-year periods from the standpoint of morbidity. Then, thinking that since cesarean section furnishes such a high febrile morbidity rate we should eliminate all sections, we have shown this comparison also.

Since the group of 500 cases that were used in our preliminary study are included in these figures, we take the liberty to show table 4, which includes a more detailed description of the morbidity in that group.

Table 5 covers the fetal mortality for the past six years, and, since the obstetric mortality shows a slight increase during the period when pentobarbital-sodium and scopolamine hydrobromide were used, we separated the charts, and in table 6 is given the fetal mortality of the group in which the mothers received these drugs.

A more detailed description of the twenty-two unavoidable deaths is given in table 7 and a detailed description of the nine cases of obstetric mortality follows.

OBSTETRIC FETAL MORTALITY

CASE 1.—A baby, weighing 8 pounds 2½ ounces (3,700 Gm.), was born after a difficult labor of sixteen hours, the second stage lasting five and one-half hours. The mother received pentobarbital-sodium 6 grains (0.4 Gm.), and scopolamine hydrobromide ¼<sub>50</sub> grain (0.0004 Gm.), at 1:45 a. m.; pentobarbital-sodium 1½ grains (0.1 Gm.) at 3 o'clock and again at 7:30, a combination of thymus extract and hypophysis extract, 3 minims (0.2 cc.) at 2:35 p. m., and at 3:40 there was a large brown emesis during the anesthetic; the mother became cyanotic and carbon dioxide oxygen was given. The baby was delivered at 3:45. Resuscitation was difficult; respirations were shallow, rapid and irregular; breathing was of the abdominal type and spastic. The clinical diagnosis was cerebral hemorrhage (severe). The baby died in thirty-six hours. The postmortem diagnosis was asphyxia neonatorum.

CASE 2.—Stillbirth resulted after a twelve hour labor. The baby was large. The pelvis was small and it was a very hard midforceps delivery, much difficulty being encountered with the shoulders. The weight was 9 pounds 12¾ ounces (4,445 Gm.).

Total.....	20

The postmortem diagnosis was laceration of the tentorium and pulmonary atelectasis. The mother received pentobarbital-sodium 7½ grains (0.5 Gm.) and scopolamine hydrobromide ¼<sub>50</sub> grain at 3:15 a. m.; pentobarbital-sodium 1½ grains at 4:50; a combination of thymus extract and hypophysis extract 3 minims at 6:40, and the baby was delivered at 11:40.

CASE 3.—This was a low cervical cesarean section. There was no engagement after twenty-four hours of labor. The pelvis was generally contracted. The mother received pentobarbital-sodium 7½ grains and scopolamine hydrobromide ¼<sub>50</sub> grain at 12:30 p. m.; pentobarbital-sodium 1½ grains at 1:30, 2 o'clock, 4 o'clock and again at 7:30; morphine sulfate one-

fourth grain (0.015 Gm.) at 9:35, atropine sulfate  $\frac{1}{150}$  grain at 7:20 a. m. and morphine sulfate one-sixth grain at 8:10. From 4:30 to 9:30 p. m. on the previous day 16 ounces of ether had been given by inhalation for attacks of pain. At 9 a. m. the baby delivered, weighing 7 pounds 14 ounces (3,573 Gm.). The postmortem anatomic diagnosis was high grade passive hyperemia and edema of the brain; ecchymotic hemorrhages of the thymus, pericardium and pleura, and cyanosis of all the thoracic and abdominal organs and of the skin of the surface of the body. The chief diagnosis was asphyxia neonatorum.

CASE 4.—Mrs. K., a primipara, three weeks overdue, was delivered of a baby 47 cm. tall. The patient was not toxic. Induction two weeks previously failed. Induction was again attempted with 2 ounces (60 cc.) of castor oil at 6 a. m., 10 grains (0.6 Gm.) of quinine at 7 o'clock and 5 grains (0.3 Gm.) at 7:30. She then received 3 minims (0.2 cc.) of solution of posterior pituitary at 10:45 and again at 11:10. A bag was "inserted" at 5:30 p. m. One third grain (0.02 Gm.) of a mixture of opium and alkaloids was given hypodermically at 8:05. The fetal heart tones were poor and the bag was taken out at 9:05. The mother received 3 minims of solution of posterior pituitary at 9:32 and pentobarbital-sodium  $7\frac{1}{2}$  grains at 11:50. At 5:45 a. m. the pulse was 80 and the cervix dilated only 3 cm. At 10 o'clock atropine  $\frac{1}{150}$  grain was given hypodermically and a low cervical cesarean section was done at 11:02. The uterus was packed; hemorrhage occurred at 2:40 p. m. The patient had a chill, which was treated by transfusion at 4 o'clock. The temperature was 102 F. and the pulse 120. The diagnosis was atelectasis.

CASE 5.—The baby was born at full term and weighed 6 pounds 5 ounces (2,864 Gm.); there was a premature rupture of the bag of waters. The baby was born dead. The fetal heart beat had been satisfactory fifteen minutes before. There was velamentous insertion of the cord.

CASE 6.—A primipara at term delivered a baby by breech presentation weighing 6 pounds 5 ounces (2,864 Gm.). A torn tentorium and brain hemorrhage were found.

CASE 7.—A primipara had a toxic thyroid and was in the hospital one month previously. The baby, weighing 5 pounds 7 ounces (2,467 Gm.), delivered spontaneously at full term after labor of nine and one-half hours, with episiotomy. The tentorium was torn.

CASE 8.—A primipara after induction delivered at term a baby weighing 8 pounds 4 ounces (3,742 Gm.), with persistent ductus arteriosus and hydronephrosis.

CASE 9.—A quartipara was seventeen days past the date due in her first pregnancy in eleven years. Induction with castor oil and quinine failed, July 8, 1933. Fairly hard contractions persisted on and off for three and one-half days. The patient was given a mixture of opium and alkaloids and sodium amylal on and off for relief. July 11 one-third grain of a mixture of opium and alkaloids was given hypodermically at 1 p. m. and 3 grains of sodium amylal at 9:30. July 12, 3 grains of sodium amylal was given at 12:30 a. m. and again at 2:55, one-sixth grain of a mixture of opium and alkaloids hypodermically at 10:40, 6 grains of pentobarbital-sodium at 11:15 and  $1\frac{1}{2}$  grains

at 11:45. There was a rapid, unexpected delivery of a baby girl weighing 6 pounds 13 ounces (3,091 Gm.), at 12:15, a stillbirth. The baby did not breathe. The mother had a hemorrhage of 400 cc. after the third stage. The uterus was packed. Shock was treated by 500 cc. of acacia solution by vein and 1,000 cc. of Ringer's solution subcutaneously.

## COMMENT

Of the foregoing nine cases classified as obstetric fetal mortality, we feel that cases 1, 3, 4, 8 and 9 were influenced by the administering of various drugs. Cases 1, 3 and 4, however, can probably more justly be laid to faulty obstetric judgment as well as to the incorrect use of pain-relieving drugs. Case 9 constitutes a poorly handled case from the standpoint of pharmacology. Certainly no obstetric patient should receive a combination of one-half grain (0.03 Gm.) of a mixture of opium and alkaloids, 9 grains (0.58 Gm.) of sodium amylal and  $7\frac{1}{2}$  grains (0.5 Gm.) of pentobarbital-sodium during the twenty-four hours preceding the birth of her baby. An autopsy was done in all nine cases. Case 8 is included in the mortality influenced by drugs, regardless of the observations made at autopsy, because the hydronephrosis was not severe and many babies are found with persistent ductus arteriosus. The combination of induction and anesthesia may have been the cause. We have used the same combination of procedures many other times without any untoward effect.

Pediatric experience with the use of pentobarbital-sodium and scopolamine hydrobromide has failed to develop any serious objection. The new-born infant of a mother to whom this anesthetic was administered presents a definite clinical picture so distinct that not infrequently the physician is able to state "pentobarbital-sodium" or "no pentobarbital-sodium" without knowledge of the facts. Such an infant is somnolent, flaccid and pale. A slowing of the heart rate to as low as from 80 to 90 beats per minute may occur. Respira-

tions are shallow, there is little or no objection to handling, and vigorous crying is absent. The Moro reflex is partially suppressed. Indifference to the taking of fluids and to nursing is often present. External heat may be necessary to maintain a normal body temperature. Various degrees of this state exist, of course, depending on the dosage of the drugs and the time relative to delivery.

First contacts with such infants caused much pediatric alarm. Continued experience has shown that a normal, pink baby with a vigorous cry and usual

spasticity may be expected in from one to two days, comparable to other deep anesthesia. Personal communications from twelve pediatricians having the frequent opportunity of caring for babies at whose birth pentobarbital-sodium was used, asked if its effect was "such that it would cause us to decide to discontinue its use," were as follows: nine were favorable to its continued use, three were noncommittal, none were unfavorable. Factors mentioned were somnolence

(eight), indifference to the taking of fluids and to nursing (five), bradycardia (four), pallor (three), flaccidity (two) and subnormal temperature (one).

One of us (R. B.) has studied random selections from his case records, seeking to determine the effect on the weight loss of the first few days of life and the relation of the home-going weight to the birth weight. No effect could be demonstrated, as summarized in table 8. He has also studied the incidence of breast feeding in "pentobarbital-sodium" and "no pentobarbital-sodium" infants, as presented in table 9. Apparently, infants born of mothers under this anesthetic stand a somewhat lesser chance of being breast fed. The difference, however, is very small. Perhaps the initial indifference to nursing may be a factor.

In February 1936 we sent letters to the last 500 women to whom we had given pentobarbital-sodium and scopolamine hydrobromide during labor and asked them to reply, stating their opinions of the procedure based on their own individual experience. We received 201 replies and we have tabulated their answers in table 10.

Of the three letters from those against the use of pentobarbital-sodium and scopolamine hydrobromide in labor, one came from a patient who received no benefit from the drugs whatever. She stated emphatically that the pains were so severe when she received the medication that she could not even see what color the capsules

were and that they did not relieve her suffering. The second was from a mother having her second baby, who was disappointed because she did not awaken immediately after delivery to enjoy the sight of her new-born infant. The third objected to its use because the following day she was somewhat drowsy. Many of the letters that were received were from women who had had from three to six babies. A number from this group approved of this method of pain relief because it not only relieved the pains but enabled them to sleep and to escape the nervous shock which so often follows the delivery of the baby. They were of the opinion that rest and sleep following labor enabled them to recuperate much more quickly.

## CONCLUSIONS

1. Pentobarbital-sodium and scopolamine hydrobromide were used to allay the pain of labor in 1,415 cases, with a maternal mortality of 0.07 per cent, a gross fetal mortality of 2.19 per cent, an obstetric fetal mortality of 0.64 per cent and a maternal morbidity rate of 5.08 per cent.

2. Maternal mortality and morbidity are not increased.

3. Infant mortality is not increased.

4. Fetal morbidity is increased if one considers the somnolence, flaccidity and bradycardia produced in the infant. This condition, however, has not led to an increase in fetal mortality.

5. The method was used in 62 per cent of the women admitted while this study was in progress. This method, in common with all methods of pain relief, is not universally applicable. Whether it should be given or withheld should be decided by the obstetrician.

6. Since constant and intelligent observation of the patient and baby are essential, it is a procedure for the well organized hospital only. It should not be used in the home.

7. The reaction of the patients toward the use of these drugs for relief of pain in labor seems quite favorable.

8. Our results with this method have been sufficiently satisfactory to warrant its further use.

636 Church Street.

THE RELIEF OF LABOR PAINS BY  
THE USE OF PARALDEHYDE  
AND BENZYL ALCOHOL

HOWARD F. KANE, M.D.

AND

GEORGE B. ROTH, M.D.

WASHINGTON, D. C.

The ideal agent or combination for obtaining analgesia and amnesia during labor should be, first of all, safe for both mother and child. It should not unduly prolong labor and should give relief from pain early, as well as produce satisfactory analgesia and amnesia in a high percentage of cases. Moreover, it should be easily administered and adequately retained by the patient. Finally, it should be free from objectionable side actions, such as (a) excitement during the induction and recovery stages, (b) nausea and vomiting, (c) deleterious effects on the heart, liver, kidneys, lungs and respiratory center and (d) local damage to mucous membranes.

Further experience with a combination of paraldehyde and benzyl alcohol leads us to believe that such a mixture closely approaches this ideal and accomplishes more with fewer undesirable reactions than any other of the existing methods of relieving the pains of labor, thus confirming our preliminary report<sup>1</sup> presented about two years ago.

## SALIENT CHARACTERISTICS OF THE DRUGS

Paraldehyde ( $\text{CH}_3\text{CHO}$ )<sub>3</sub>, a polymer of acetaldehyde ( $\text{CH}_3\text{CHO}$ ), is a colorless liquid, soluble in

From the Departments of Obstetrics and Gynecology, and of Pharmacology and Therapeutics, George Washington University School of Medicine.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

1. Kane, H. F. and Roth, G. B.: Tr. Am. A. Obst. Gynec. & Abdomin. Surg., 1934, p. 201; Am. J. Obst. & Gynec. 29: 336 (March) 1935.

water to about 10 per cent. It burns readily, has a disagreeable taste, possesses a characteristic pungent odor and is rather irritating to mucous membranes. However, it does not precipitate proteins unless contaminated with acetaldehyde. Its irritant action on mucous membranes is therefore probably due to its ready volatility and penetration into the loose tissues, thus resembling somewhat the volatile oils in this respect.

Pharmacologically it resembles ethyl alcohol rather closely but it is a more powerful narcotic than the corresponding primary alcohol. In small dosage (2 cc.) taken at the end of the day it acts as a hypnotic, but to secure this effect in an excitable nonpuerperal patient about an ounce (30 cc.) is required. The sleep that it produces closely resembles normal sleep; there are no marked after-effects and the sleep is usually refreshing. It was introduced into therapeutics as a hypnotic by Cervello in 1884.<sup>2</sup>

Paraldehyde is rapidly absorbed from mucous membranes, particularly when given undiluted and, less readily, when given in oils. Some of it is destroyed in the body, but the greater part is excreted as such by the lungs and kidneys, neither organ being damaged by it.

Benzyl alcohol ( $C_6H_5 \cdot CH_2OH$ ) is an aromatic alcohol, an isomeride of cresol which occurs naturally in certain balsams and oleoresins. It is a colorless fluid possessing a pleasing odor, slightly soluble in water (about 4 per cent) and readily miscible with paraldehyde. The pure substance is irritant as well as anesthetic when applied to mucous membranes. It will precipitate proteins but in 1:10 dilution with paraldehyde does no damage to the tissues. It is about half as toxic as cresol, being rapidly eliminated in the urine as hippuric acid.

Macht,<sup>3</sup> who introduced benzyl alcohol into therapeutics as a local anesthetic in 1918, found that the drug itself could cause analgesia through its central action when used in large but safe amounts in experimental animals.

It is absolutely essential that only pure drugs be used. The paraldehyde should meet the requirements of the United States Pharmacopeia and the benzyl alcohol those of New and Nonofficial Remedies. Paraldehyde may be contaminated with acetaldehyde, which reduces its hypnotic action and which, by precipitating proteins, may cause local injury to tissues.

As the taste of paraldehyde renders it objectionable to the majority of patients, the oral route for administration is not serviceable. Neither paraldehyde nor benzyl alcohol is suitable for subcutaneous use, as necrosis is frequently produced when so given. Paraldehyde is only mildly irritant to mucous membranes, but in many cases the irritation is sufficient to cause its expulsion when given by rectum. To insure retention of the drug, benzyl alcohol is added for the purpose of anesthetizing the rectal mucosa until the paraldehyde shall have been absorbed. By this means one avoids dilution of the paraldehyde with oil, which adds to the bulk of the injection, delays absorption and is frequently not retained.

The earliest report of the use of paraldehyde as the basic agent in labor was that of Rosen<sup>4</sup> in 1932. In 1934 Colvin

and Bartholomew<sup>5</sup> presented a thorough analysis of a series of 100 cases in which the drug was employed. The former, however, preceded the injections of paraldehyde in oil by the oral administration of pentobarbital-sodium or sodium amytal; the latter used sodium amytal. To us it has seemed advisable to avoid the barbiturates, as we believe that they are more toxic, are more apt to cause excitement and add nothing of value which cannot be provided by paraldehyde. The recent report of Foote<sup>6</sup> on paraldehyde by rectum as a preanesthetic agent lends support to this belief. Comparing it with the barbiturates, he states: "It is safer, more rapid and certain in action, it can be used in bad risks, the postoperative state is quieter and the sleep more prolonged, complete amnesia is obtained and the sleep is refreshing."

#### PHARMACOLOGIC EXPERIMENTS ON UTERINE ACTIVITY

The main aspects of the pharmacology of paraldehyde have been described by Cervello<sup>2</sup> and others, summaries of which may be found in any standard textbook of pharmacology.

Nothing, however, seems to have been written about its effect on uterine motility. Accordingly we made a study of its effect on both isolated and intact uteri and found that paraldehyde in comparatively concentrated solution (1:12,500) was stimulating to the excised uterus of the guinea-pig and without effect on the rabbit uterus, while a 1:5,000 solution was usually depressant to both longitudinal and cervical segments of either rabbits or guinea-pigs.

In the intact rabbit anesthetized with paraldehyde strong rhythmic uterine movements were present, being uninfluenced by 10 cc. of 8 per cent supplemental paraldehyde given intravenously.

Rhythmic uterine movements were obtained also in the paraldehyde anesthetized cat, but they are weaker than in the rabbit, a difference which was regarded as due to species rather than an effect of the drug.

Pronounced rhythmic movements were produced in the cat by a small amount of solution of posterior pituitary. When magnified in this manner the movements were uninfluenced by the intravenous administration of an 8 per cent solution of paraldehyde and only slightly depressed (mainly in rate) by doubling this quantity.

Benzyl alcohol was found to be somewhat more depressant to isolated uteri than was paraldehyde, the depression of the cervix usually occurring before that of the horn.

When benzyl alcohol was given intravenously to either rabbits or cats anesthetized with paraldehyde, it was without effect on the uterus in as high a dosage as 3 cc. of a 3 per cent solution.

When used in combination with paraldehyde on isolated uteri of the rabbit and guinea-pig, simple summation rather than potentiation of effect resulted.

From these studies they concluded that both paraldehyde and benzyl alcohol were but mildly depressant to uterine muscle, the former being less depressant than the latter.

## SAFETY

Paraldehyde is commonly stated to be the least toxic of the hypnotic drugs.<sup>8</sup> The amount herein recommended has been found to be the minimal effective dose.

Benzyl alcohol also is of low toxicity; moreover, the quantity which is employed in this mixture is so small that its general narcotic effect is negligible.

The mixture has been used in the presence of heart, liver and kidney disease as well as in normal cases, with no harmful effects noted. Although the odor of paraldehyde may be present for several days on the breath of the babies, they apparently are unaffected by the drug. When ethylene is used in the perineal stage of labor, no delay in the initiation of respiration has been noted. After delivery under ether, however, there has been a tendency to mild apnea, but never to a dangerous degree. It would seem that the combination of paraldehyde and ether is not ideal for the baby.

## ADMINISTRATION EARLY IN LABOR

In most methods of pain relief, emphasis is placed on the withholding of analgesics until the cervix has reached a certain stage of dilatation or until the contractions have attained a frequency arbitrarily determined. The paraldehyde-benzyl alcohol mixture is given as soon as the patient complains of pain, without regard to the cervix, contractions, parity or condition of the membranes. Gwathmey and McCormick,<sup>9</sup> in their modification of Gwathmey's original method,<sup>10</sup> adopt the same plan.

## EFFECT ON LENGTH OF LABOR

In estimating the length of labor, it has been necessary to disregard the usual division into first and second stages. In most instances one stage merges imperceptibly into the other, and frequently the bulging perineum has been the first indication of full dilatation of the cervix. Although laboratory experiments have shown that paraldehyde has little effect in various animals, clinically it seems to lengthen somewhat the intervals between pains. This lengthening seems to be beneficial, probably through allowing time for the fatigued muscle to recover its tonus.

The mixture of paraldehyde and benzyl alcohol apparently softens the cervix and hastens dilatation. These factors seem to be responsible for the impression that labor has been somewhat lengthened in some cases and shortened in others.

The average time between the first rectal instillation of the mixture and the appearance of the presenting part at the outlet has been, in primiparas, seventeen hours and forty-one minutes; in multiparas, eleven hours and fifty-five minutes.

The duration of labor in primiparas ranged from one to fifty hours; in multiparas, from one-half to twenty hours.

The number of rectal instillations given, per case, was from one to ten, the average being four in primiparas and two in multiparas.

## RETENTION OF THE SOLUTION

Retention of the solution is practically always complete. When it is not retained it is almost certain evidence that the patient is in the second stage of labor with the presenting part low in the pelvis.

## ANALGESIA AND AMNESIA

Ordinarily the patient, when once under the influence of the paraldehyde-benzyl alcohol mixture, sleeps quietly, perhaps turning and moaning with each contraction. In these cases analgesia is presumed to be complete. Some patients will seem to become fully awake at each pain, will talk lucidly and even complain of suffering. When this occurs there is evidently some impression on the brain, but after labor there is absolutely no recollection of what has taken place. As amnesia is complete, these cases are regarded as having been successful. A few women remember unrelated events, such as the first inhalations of gas, remarks made by the attendants, or catheterization, but seldom do they recall having suffered. When labor is of less than three or four hours' duration and of the tumultuous type, one severe pain following another at intervals of two or three minutes, it must be admitted that the paraldehyde-benzyl alcohol mixture has little or no effect.

It is interesting to note that the patient may not go to sleep until after a second rectal instillation, but amnesia usually extends back to the first injection.

## FREEDOM FROM OBJECTIONABLE SIDE ACTIONS

Excitement to the point of tossing about or requiring restraint always indicates that the dose has been insufficient, that the effect is wearing off, that the presenting part is approaching the perineum or, as is most frequently the case, that the rectum contains fecal matter which is interfering with absorption of the drugs.

Nausea and vomiting have not been noted from the use of paraldehyde-benzyl alcohol.

Laboratory experiments have shown, and clinical experience has confirmed the fact, that there are no deleterious effects on the heart, liver, kidneys, lungs or respiratory center. As paraldehyde is excreted largely through the lungs, it is perhaps contraindicated in the presence of pneumonia, but it has been used successfully in one case of active pulmonary tuberculosis. No patient has shown evidence of proctitis.

## TECHNIC OF ADMINISTRATION

1. Of particular importance is the thorough cleansing of the lower part of the bowel and rectum with a soapuds enema followed by irrigations with physiologic solution of sodium chloride until the return is absolutely clear.

2. The dose of paraldehyde is 1.2 cc. to each 10 pounds (4.5 Kg.) of the weight of the woman at the beginning of labor.

3. The dose of benzyl alcohol is always 1.5 cc. As the action of this drug is largely that of a local anesthetic, the dose does not vary with the weight of the patient.

4. To the required amount of paraldehyde is added 1.5 cc. of benzyl alcohol and the mixture is instilled by gravity into the rectum by means of a funnel and a large catheter, which is inserted for a distance of about 4 inches (10 cm.). As the solution disappears it is followed by not more than 30 cc. of physiologic solution of sodium chloride to wash out the catheter and distribute the drug. The bulk of the injection is so small that the instillation can be made between two contractions. While there is seldom any tendency for the patient to expel the solution, it is recommended that during at least two pains the buttocks be compressed and the patient be asked not to "bear down."

8. Miller, A. H.: *Anesth. & Analg.* 15: 14 (Jan.-Feb.) 1936.  
9. Gwathmey, J. T., and McCormick, C. O.: *Ether-Oil Rectal Analgesia in Obstetrics*, J. A. M. A. 105: 2044 (Dec. 21) 1935.  
10. Gwathmey, J. T.: *New York State J. Med.* 95: 1101, 1913.

5. Paraldehyde-benzyl alcohol is given as soon as the patient complains of pain. The dose, and always the full dose, may be repeated if necessary, one and one-half hours after the first. As labor progresses it will be found that the effect of each successive injection is more lasting, the intervals between repetitions becoming three, four or five hours.

6. If the patient is awake one-half hour after the initial instillation of the rectal solution, one-fourth grain (0.015 Gm.) of morphine is given subcutaneously. It is rarely necessary to repeat the morphine, although in long labors it has occasionally been repeated with no apparent harm.

7. When several doses of the mixture are given, the rectum should be irrigated with physiologic solution of sodium chloride before each alternate instillation.

8. To minimize dehydration, a glass of orange juice or water should be given before each injection of paraldehyde-benzyl alcohol. The patient is usually capable of cooperation to the extent of drinking; otherwise dextrose, intravenously, may be given.

9. Since the patient is not conscious of bladder distention, catheterization is performed every eight hours.

10. Too much emphasis cannot be placed on the necessity for repeating the rectal injection when the patient begins to awaken, not after she has become restless.

CLINICAL OBSERVATIONS

The degree of success depends somewhat on the length of labor. In the case of a multipara, in labor for only one or two hours, this method of treatment is practically useless; to the primipara with a slowly progressing occiput posterior it gives complete relief. The fact that the patient is not suffering lessens the temptation to early and perhaps dangerous interference with labor.

Observation of these cases has strengthened the belief that the value of voluntary contraction of the abdominal muscles has been greatly overestimated. Although

TABLE 1.—Results in Six Hundred and Eleven Cases Studied

these women are not allowed to strain and pull on straps, the second stage of labor progresses as rapidly as in cases in which the patients attempt to cooperate.

In certain cases, particularly in multiparas, it is possible to accomplish spontaneous delivery without a general anesthetic. As a rule, however, the patients are only semiconscious and it is difficult to maintain aseptic technic. Delivery by outlet forceps under a general anesthetic, preferably ethylene, is therefore recommended in cases which ordinarily would need no assistance.

Some methods of analgesia are said by their proponents to be safe for use in home deliveries. We feel, as do Irving and his associates,<sup>11</sup> that any person

who has been rendered unconscious by drugs should constantly be under the observation of a trained attendant.

This method, we believe, should be administered in the home only when the physician is prepared to remain with the patient throughout the duration of labor.

RESULTS

In estimating the value of the paraldehyde-benzyl alcohol mixture as an agent for securing analgesia and amnesia, the cases have been separated into five groups. Group A consists of those patients who have slept quietly throughout labor. In group B are those patients who have moved about, at times seemed to be completely rational and complained of pain; amnesia, how-

ever, in this group is complete. The patients who remember unrelated events but no pain constitute group C. Those who remember having had some pain but whose suffering was greatly relieved are placed in group D. In group E are those who received no benefit from the method.

Table 1 shows the results in the 611 cases that we have studied. More than 1,000 additional patients have been treated by other physicians according to the technic described in this paper. While statistics in these cases are not available, those who have observed them agree that the results as tabulated fairly represent their experience.

Complete relief from the memory of pain was accomplished in 89.7 per cent, partial relief in 2.6 per cent and no relief in 7.7 per cent. All but four of the patients in groups D and E were in labor less than four hours.

From table 2 it will be noted that there were 3.3 per cent of stillbirths and neonatal deaths; three, or less than 0.5 per cent, were from causes undetermined and may be charged to the method. However, since two such deaths had occurred in our preceding 1,000 cases before any anesthetic had been given, it is possible that the use of paraldehyde and benzyl alcohol may not have been the cause.

SUMMARY

1. The combination of paraldehyde and benzyl alcohol administered rectally produces complete amnesia without unduly prolonging labor in practically all cases in which labor is of more than four hours' duration, without causing ill effects on either mother or child.
2. The solution is retained without difficulty except when the presenting part is pressing on the rectum.
3. There have been no cases of proctitis or other evidence of local damage to tissue.
4. Excitability of the patient is present only when the technic of administration has not been properly carried out.
5. These women are not subjected to the fatiguing exertion of "bearing down" and pulling on straps; they are spared the psychic shock of pain; they have

11. Irving, F. C.; Berman, Saul, and Nelson, H. B.: Surg., Gynec. & Obst. 58:1 (Jan.) 1934.

no memory of suffering, and they sleep quietly for from six to twelve hours after labor. As a result, they awaken actually refreshed.

6. Increased experience with this method of pain relief has shown that success depends largely on strict attention to the details of administration.

### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. KREBS, WULFF AND WASSERMANN,  
DRS. GALLOWAY, GRIER AND BLESSING, AND  
DRS. KANE AND ROTH

DR. BUFORD G. HAMILTON, Kansas City, Mo.: The majority of women can be delivered safely without sedatives—probably most women would be in better condition if morphine were used judiciously. Women may be given sedatives and have no remembrance of their labor; unfortunately, this cannot be done in every case. The successful termination of labor depends on the management of each stage of labor. Sedatives do interfere when not properly supervised. That there is a close relation between sedation and intervention is well known. It is also known that intervention is exacting its toll of lives of American women. The point that concerns me is that I do not know the threshold of pain and that I cannot measure the force of pain. Measuring the dosage for each individual patient has been my problem. Two patients are given sedatives at what is considered the ideal time. Both deliver normally in four hours without any remembrance of pain. Later, two similar patients are treated in the same way only to be delivered artificially. I cannot think the patient was at fault but that it was the administration of sedatives. In discussing this situation with outstanding obstetricians I find that they have the same problems. One can only conclude that American obstetrics has become a competitive problem to please women instructed by lay magazines. Intervention because of fetal distress is a part of the picture. All have experienced these anxieties and have felt that sedatives produced the condition. For these reasons it would seem that our only honest promise to patients must be sedatives in such doses as will be safe for both the mother and her unborn child. The necessity of supervising all patients given sedatives must never be lost sight of, since obstetric success can be measured only by results.

DR. JOSEPH B. DE LEE, Chicago: I feel very decidedly that the magazines and the competitive practices of doctors have increased the fear of having a baby in the minds of the public. Anesthesia may be divided into anesthesia of the first stage, or analgesia, and anesthesia of the second stage. The first stage anesthetics or analgesics are morphine and scopolamine, so-called twilight sleep. The original twilight sleep is passé. Nobody uses that now because in the best of hands in Europe it showed an irreducible mortality of 1 per cent. I am going to take up the personal element in the use of drugs in order to produce a more or less painless labor. The success of all anesthetics depends on the doctor. Abnormal states of the mind can cause spastic conditions of unstriated muscular organs, such as the stomach, the heart and the colon. Why cannot the uterus be affected by the mind? Many patients are cured by faith in their doctor, and it makes little difference what medicine he gives. Hippocrates said "The physician amuses the patient while the gods cure him." The notorious Mr. Coué showed what could be done by faith and nature. Suggestion is a powerful adjunct to all our remedies and we doctors have let the cultists run away with it. I have not seldom prescribed 20 grains (1.3 Gm.) of sodium bromide for sleep, telling the patient that the effects of the powerful sedative would last two or sometimes three nights. Pure suggestion has made these women sleep through two or three nights. I always apply the psychologic laws of suggestion in my practice, and I have even employed hypnotism. One has to be careful in the use of hypnotism, especially to avoid catalepsy, which is very dangerous. Those who try hypnotism should remember to use posthypnotic suggestion. In Heidelberg some years ago the experiment was made in the seventh month of pregnancy in which the woman was given intense suggestion of painless labor and that carried through until term. Suggestion is a

matter of personality. Its success depends on faith. Faith is given to a doctor who has, as King Solomon said, an understanding heart. If one can bring the patient's mind into a proper evaluation of the nature and purposes of labor, the first stage can be conducted with a minimum of anesthetic agents, and it is not a far cry to say that perhaps contraction rings will be to a large extent eliminated, labor assuming a more normal course.

DR. JOSEPH L. BAER, Chicago: From the conclusions of the authors we must find that there is still much lacking in what they hope for from the methods they employ. If that is so, the method employed is to a definite degree defective. There is no doubt in my mind that beginning with the propaganda tour of Drs. Krönig and Gauss, publicized by *McClure's Magazine* twenty-odd years ago, there was infiltrated into American womanhood this demand for painless labor which has been timidly yielded to by the American medical fraternity. It behooves us to stem that tide in the interest of our obstetric patients and their babies. In Michael Reese Hospital ever since my connection with it a little over thirty years ago, the standard relief of women who need relief in labor has been morphine. Morphine still occupies, in my opinion, the front rank as an analgesic in labor. Over 50 per cent of all women in the United States are delivered in the home, and of those delivered in institutions only a very small group is in institutions sufficiently well regulated and sufficiently well nursed to warrant the application of these various methods with which we are all experimenting, and which require the maximum of constant medical and nursing care. Therefore, for American women in general we must still urge the safe, sane method of obstetric analgesia when indicated, and, I repeat, morphine offers that relief. Every woman in labor is a potential emergency major surgical risk wherever she may be. To mask her symptoms under the prolonged effect of powerful amnesic or analgesic agents and leave her to the observation of relatives or an inadequate hospital staff when she is a potential emergency major surgical risk I regard as culpable evasion of responsibility not justified by the clamor of the uninformed patient.

DR. RUDOLPH W. HOLMES, Chicago: I feel that an obstetric utopia will come when we shall have a drug which shall be utterly innocuous to mother and child, shall have no influence on the phenomena of labor, shall cause no interference with the intensity of contractions or their rhythmic course, and shall not rob the woman of those voluntary efforts which are so essential during the expulsive period of labor. Not one of the drugs which have been popularized of late meets these criteria. Some are highly inimical to mother or baby, or both, and all demand an excessive incidence of operative intervention. I have the misfortune to be among the first to bring scopolamine to the United States, in 1901. I employed it on various patients and with disastrous effects. Its wide exploitation in 1913 under the name of twilight sleep prompted me to try the drug again, for various pharmaceutical houses declared that the previous disasters were from the use of impure drugs. At this time I had documentary assurance that scopolamine was unobtainable. In view of the fact that the recovery of scopolamine from scopolus was so expensive, and in view of the fact that hyosine was chemically, spectroscopically and physiologically identical in action to scopolamine, the only marketed product was hyosine under the label of the former. In each trial I found numerous instances of the untoward effects, with fetal deaths greater than in other means of allaying pain. I feel that hyosine in combination with morphine is just as great a menace today as it was in 1913. We all know that obstetric mortalities have not decreased in twenty years. Institutional deaths are essentially the same as they were 100 years ago. I have the results of a study comprising 240,000 births in 490 hospitals, with a total maternal loss of 0.8 per cent. The Rotunda Maternity a hundred years ago had a maternal loss of 0.9; this rate is infinitely less than that of some hospitals of modern times: 2 per cent, 4 per cent were not infrequent, and in one it was over 7 per cent. Modern obstetric practices have transferred, in comparison to the Rotunda figures, stillbirths to neonatal deaths, the net result being that fetal (infant) losses are as they were a hundred years ago. I cannot see that it is good obstetrics in a highly organized hospital to paralyze a parturient with drugs, subject her to the expense of engaging a special

nurse, and then perforce use operative interventions to the extent of 85 per cent of all labors.

DR. NICHOLSON J. EASTMAN, Baltimore: From a statistical point of view one can be readily convinced that the analgesic methods yield satisfactory results, since amnesia is produced in a substantial majority of the cases and since the end results, both for mother and for child, compare favorably with our best standards. We must, however, face squarely the fact that both barbiturate analgesia and scopolamine-morphine analgesia affect the infant profoundly. This statement is based on the following considerations: 1. Barbiturates pass rapidly from mother to fetus. In a dog or in a rabbit they are demonstrable in the fetus within fifteen minutes after they have been given to the mother. 2. In a series of Baltimore cases in which pentobarbital-sodium was given in doses of from 6 to  $7\frac{1}{2}$  grains (0.4-0.5 Gm.), the amniotic fluid was meconium stained in 16 per cent of the cases. In an additional series in which to the pentobarbital-sodium analgesia were added morphine, one-sixth grain (0.01 Gm.), and rectal ether, 75 cc., the amniotic fluid was meconium stained in 40 per cent of the cases. The end results in these infants were satisfactory, but the inference to be drawn from this high incidence of meconium stained amniotic fluid would seem clear enough. 3. Since the time of Ahlfeld it has been suspected that the fetus in utero makes respiratory movements, and Ahlfeld advanced the view that the onset of respiration occurs—at least the onset of respiratory movements—not at the moment of birth but sometime back in intra-uterine life just as the cardiac action does. During the past year, Snyder and Rosenfeld of our institution have demonstrated intra-uterine respiratory movements of the fetus in the rabbit, the cat, the dog, the guinea-pig and the monkey. These thoracic movements, which are clearly visible through the intact uterine wall, are rhythmic in character, of a rate between 20 and 60 per minute, and are obviously of a respiratory nature. Now if, while one is watching these rhythmic thoracic excursions, the mother animal is given either morphine or barbiturates, these movements stop at once. 4. As a result of the observations of Irving, Berman and Nelson of Boston, it is known that babies born of mothers who have had neither analgesia nor anesthesia cry immediately in about 98 per cent of the cases; babies born of mothers who have had nitrous oxide analgesia breathe immediately in about 80 per cent of the cases, whereas babies born of mothers who have had scopolamine-morphine or barbiturate analgesia cry immediately in from 33 to 65 per cent of the cases. In view of these circumstances it would seem justifiable to conclude that these analgesics exert a depressing effect on the baby. Full-term infants seem to withstand this satisfactorily, provided there are no other complicating factors.

DR. GEORGE J. L. WULFF, St. Louis: Drs. Krebs, Wulff and Wassermann have shown the fetal mortality in our study of 4,000 consecutive deliveries. Frequently the objection is made that twilight sleep causes increased fetal apnea. Last year I studied a series of 1,000 consecutive deliveries at St. Louis Maternity Hospital, with regard to those factors which I felt might be said to cause delayed cry and respiration. Among these were included the type of seminarcois used, the type of anesthetic used and the incidence of operative deliveries. Premature infants, twins and those delivered by cesarean section were omitted from the series for obvious reasons. Of the total series, 16.3 per cent of the babies had delayed cry and respiration. Two hundred and seventy-five mothers had no seminarcois, and this group served as our control. Five and five-tenths per cent of these babies were apneic. In the case of the 360 mothers who received morphine with scopolamine, 24.7 per cent of the babies had a delayed cry; in 188 cases with dilauid and scopolamine, 24.5 per cent; in 120 cases in which sodium amylal was used with scopolamine, 6.7 per cent; in forty-seven cases in which pentobarbital-sodium and scopolamine were used, 8.5 per cent; in nine with sodium alurate and scopolamine, 11.1 per cent, and no apnea in the single case of oral sodium with scopolamine. Using 5.5 per cent as our standard without scopolamine, it seems obvious that the use of either morphine or dilauid with scopolamine probably increases the incidence of apneic babies, while in the cases in which the barbiturates were used the incidence more nearly approached that of the control group. The relationship of the type of delivery to fetal apnea was considered next. In the 372 cases in which

delivery was spontaneous, 13.1 per cent of the babies required resuscitation. In 557 cases in which perineal forceps were used, there was 15.9 per cent of apneic infants. Of the thirty-three cases of breech presentation, there was delayed respiration in 39.4 per cent. In thirty-six cases of vertex presentation the head was rotated with forceps from the transverse or posterior position, and 27.7 per cent of these showed definite apnea. Only two cases of version were done and both babies were apneic. The differences in this analysis may be explained by the difficulty of the procedures carried out during delivery. The last analysis compares the types of anesthetics used. Fifty-eight mothers received no anesthetic and 8.6 per cent of these babies were asphyxiated. Six hundred and eighty-eight mothers received chloroform during the delivery of the infant and 16.5 per cent of the babies were apneic. Nitrous oxide was used in 223 cases, 15.6 per cent of these infants requiring resuscitation. Ether was used in thirty-one cases, and these showed a 29 per cent incidence of apnea.

DR. FREDERICK V. ENMERT, St. Louis: Dr. Siegfried Goldschmidt and I desire to introduce a method of analgesia in labor which, to our knowledge, has not been used in this country. It is a new barbiturate, sodium amyl beta bromalyl malonylurea, and is given rectally. We induce the analgesia when labor is definitely established and the cervix is dilated to two or three fingerbreadths. Ten cubic centimeters of the solution is given by means of a small catheter as high rectally as possible. The effect is noticeable after from ten to fifteen minutes, causing drowsiness and sleep between contractions. In the majority of our cases there were no signs of restlessness. We found no objectionable interference with labor in respect to frequency and force of contractions. The analgesia lasts normally from three to four hours and as long as eight hours. We saw no undesirable effects on the mother. A great number of the babies were born spontaneously, entering the world in good color and crying lustily. The explanation of this behavior is the rapidity and complete destruction of the drug in the liver, so that only traces can be found in the urine of the patient immediately after delivery. With this method we find labor hastened and the color of the patient, respirations, blood pressure and pulse unchanged. There have been no complications, except one occipitoposterior position. No postpartum hemorrhages have occurred. Thus far we have delivered twenty-five cases by this method. The average length of labor after the administration of the drug was three hours and ten minutes. The analgesia was complete in 75 per cent, incomplete in 25 per cent. The amnesia was complete in 80 per cent and partial in 20 per cent. There were no maternal or fetal deaths.

DR. P. B. RUSSELL JR., Memphis, Tenn.: I am inclined to express my appreciation to those men who think something of analgesics. Never have I found the operative incidence increased as the result of using analgesia. If a man is given relief for the pain of a passage of a ureteral stone, a woman is entitled to the same care when she suffers the agonizing pains of labor. A patient can ease through the first stage of labor without complications if the analgesia is not abused. There is no need for any operative procedure other than the low forceps; the prophylactic forceps technic as described by De Lee. This will save the structures of the perineum and there will be no lacerations and no need for perineorrhaphy or colporrhaphy, which is not the case with the spontaneous delivery.

DR. S. KENDIG WALLACE, Baltimore: I feel that obstetric analgesia should be used only in cases of prolonged labor. I want to call attention to some of the disadvantages of the methods already presented. Morphine given from four to six hours before delivery is dangerous;  $7\frac{1}{2}$  grains (0.5 Gm.) of pentobarbital-sodium at one time is quite a large dose. In the case of paraldehyde, it seems that the patient is so sound asleep that she cannot bear down, cannot void and must be catheterized every eight hours. I should like to mention the method that was presented last year in Atlantic City, the modified Gwathmey method, in which one begins with 3 grains (0.2 Gm.) of pentobarbital-sodium by mouth and gives the Gwathmey ether, quinine and alcohol by rectum a half hour later. One gets the patient asleep with the two capsules and the ether and she wakes up and has a pain and goes back to sleep. The advantage in the long labor is that there is no need to intervene. One can wait because the patient sleeps between the pains. A nurse

is not needed and the quinine stimulates the pains. The only disadvantage is the burning when the ether is given.

DR. OTTO S. KREBS, St. Louis: Thorough analysis of our results have been on record for a good many years and has shown the harmlessness of scopolamine-morphine semianarcosis in competent hands and in proper surroundings. Dr. Hamilton does not find any of the methods at hand uniformly satisfactory and rather deprecates their use. In St. Louis, some of us spend a great deal of time with our patients in labor, remaining with the woman, so far as possible, from the time active labor has begun to its completion. For the obstetrician who comes to the patient only in time to deliver her, there is no need for analgesia; but if he followed the progress of labor with her, his point of view probably would change. To be with a parturient woman for hours and not to be able to feel reasonably sure one is making the ordeal more bearable would make obstetric work intolerable to me and I would give it up. Morphine, which Dr. Baer uses entirely, we know to be the potent factor in delayed fetal respiration since 1906, further emphasized in 1915, and we have been able by modifying our technic to reduce the dosage or limit its use with improved results. Dr. Eastman reports an anoxemia and effect on intra-uterine respiration produced by various anesthetic agents and analgesics. Whether this condition in the fetus is of any danger or consequence to the child has not been established. Since we who use these agents so extensively find such uniformly satisfactory results, and since our figures in thousands of cases over twenty years show a fetal mortality comparing favorably with any and better than most clinics in this country, might not this fetal effect be a protective mechanism? Dr. De Lee states that "twilight" is "passé," that it is no longer being used in Europe. If Dr. De Lee would turn to St. Louis he would learn that it has been used safely and successfully in more than 5,000 cases there in one hospital since 1929. I was not surprised to hear Dr. Holmes's assault on the drugs. In 1923 in San Francisco he made almost the identical speech, except this time he mislaid his keynote phrase, "scopolamine, the murderous drug," which was his opinion at that time based on his experience with one case.

DR. ROBERT M. GRIER, Evanston, Ill.: I suppose I should cringe to come up on this platform after all the fear instilling remarks of some of the discussers. Their criticism is uncalled for. Pentobarbital-sodium is not a perfect drug. We have mentioned the points of disadvantage in our contraindications. Until such fantastic methods as hypnosis and the like can be used, we are satisfied with the effectiveness and safeness of pentobarbital-sodium. The figures of our results should speak for themselves. We have watched our results carefully and feel that so far it is a good analgesic in labor. Some day a better method will come into use, but we shall continue using these drugs until it does. We feel that a woman is entitled to relief from the pains of labor and that they are real and cannot be passed off lightly by the power of suggestion.

DR. HOWARD F. KANE, Washington, D. C.: The reason I tried to find some method of relieving pain in labor was not entirely to please the women but because I felt that obstetric shock was just as much an entity as surgical shock. Fear, fatigue and pain are factors in obstetric shock. I felt that if the patient could be spared the fear and the shock from pain itself she would be spared the shock and would be in better condition and a much better risk as a surgical emergency, as Dr. Baer pointed out. No method is entirely successful, but an attempt is being made to find one. These patients are in much better condition post partum. Their strength comes back sooner, they are able sooner to take care of their babies, and altogether they are in better condition. Dr. Hamilton said that these methods are not available to many women. That is true, but why deprive the women who can have it simply because some cannot?

**Nature of Hunger.**—Hunger is a primitive, elemental sensation. It is felt as a dull ache or gnawing pain, referred to the midchest region or somewhat lower. Unlike appetite, it is not associated with desire for any particular food. It does not invite men to eat, it drives them to do so.—Cannon, W. B.: *Digestion and Health*, New York, W. W. Norton & Co., Inc., 1936.

## Clinical Notes, Suggestions and New Instruments

### ENCEPHALOGRAM SYRINGE

WARREN T. BROWN, M.D., NEW HAVEN, CONN.

The accompanying drawings illustrate a simplified instrument for the withdrawal of spinal fluid and injection of air for purposes of encephalography.

The 20 cc. Luer-Lok syringe<sup>1</sup> is altered by drilling two holes in the barrel on opposite sides. A small hole, 2 mm. in diameter, is drilled just behind the 10 cc. graduation mark with its forward edge tangent to the mark. A larger hole, 4 mm. in diameter, is drilled on the under side of the barrel with its forward edge directly opposite to the back edge of the small hole on the top side of the barrel.

#### THE WORKING PRINCIPLE

With the patient in a sitting position, a lumbar puncture is done in the third or fourth lumbar space, and a pressure reading is taken. The manometer is removed, and the syringe with the plunger drawn to the 10 cc. mark is attached to the needle by the Luer-Lok device. The 10 cc. of air is injected, and the fluid is allowed to enter the syringe, pushing the plunger back

Encephalogram syringe.

by its own pressure. It may be necessary to rotate the plunger with the fingers to prevent its sticking or becoming lodged. When the end of the plunger reaches the 10 cc. mark, air enters through the small hole and the plunger can be drawn back some 6 mm. to open the larger hole and allow the 10 cc. of fluid to pour into a beaker held by an assistant. The fluid pours out in about three seconds or less and the barrel is simultaneously filled with air through the small hole on the top side. When the plunger is then pushed forward to the 10 cc. mark, the barrel chamber is closed by the plunger blocking both holes. The 10 cc. of air it contains is then injected. Should the withdrawal or injection of larger amounts be desired, the holes can be closed by the thumb and forefinger of the sterile gloved hand and released at the point desired. When the fluid has flowed out, the holes are again closed and an equal amount of air is injected.

Intermittent pressure readings may be taken by removing the syringe after injecting air and applying the manometer to the needle.

An instrument of this type has been used by me in doing air injections for encephalography in the Department of Psychiatry of the New Haven Hospital, New Haven, Conn., for a period of one year and has been found to simplify and facilitate the procedure.

333 Cedar Street.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed.

#### THE THERAPY OF (HORSE) SERUM REACTIONS

GENERAL RULES IN THE ADMINISTRATION OF THERAPEUTIC SERUMS

IN COLLABORATION WITH DR. SAMUEL M. FEINBERG

In a number of diseases, serum therapy is life saving and hence obligatory; in some instances, intravenous injection of the serum is the only mode of administration by which therapeutic results can be obtained. In some—fortunately rare—cases, serious sickness and even death may result from serum administration, particularly when improperly given by the intravenous route.

#### DIAGNOSIS

**Ordinary Serum Sickness.**—Nine or ten days after injection, a painful and itching swelling at the site of the injection is noted. Soon fever develops, accompanied rarely by nausea and vomiting. A day or two later a rash appears, which is generally urticarial and causes itching. There may also be more or less generalized edema. The joints are frequently painful and tender, although not often enlarged. Sometimes peri-articular edema and fluid in the joints occur. There is generalized swelling and tenderness of lymph nodes, with the regional ones usually the first to be involved. The urine sometimes shows albumin. Occasionally there are neurologic complications. There is usually a total diminution of the white cells, with a relative lymphocytosis. In a few days the patient is perfectly well. The whole process is annoying but almost invariably harmless.

This type of serum reaction is unpredictable, as the preliminary skin test is negative. It depends somewhat on the quantity of serum given and the rapidity with which it is administered. For instance, 90 per cent or more of white persons will react in such a manner if a large amount of serum is given intravenously. If it is given subcutaneously the percentage becomes smaller, but it also depends considerably on the dose. Thus, while 3 cc. will result in reactions in possibly 10 per cent, 30 cc. will produce them in 30 per cent, and 100 cc. will give them in 80 per cent of cases.

The reason for the incubation period is the interval required for the formation of antibodies, which at the time of serum sickness can be found in the blood. Later the skin tests become positive.

**Accelerated Serum Disease.**—If the patient has previously had a serum injection, the "accelerated" type of reaction may occur following the next injection. The symptoms are similar to those described under serum sickness, but they come on after a shorter incubation period, possibly within a few minutes, a few hours, or up to three or four days following the injection. The

manifestations may differ in no way from those previously described, but usually they are much more severe and alarming. There is a generalized erythema, with urticarial swellings. The pulse becomes weak and the blood pressure falls. Syncope or unconsciousness may result. The mucous membranes may be involved, with the production of sneezing, lacrimation, dyspnea and wheezing. Indeed there is a possibility of "allergic shock," which may terminate in death.

These reactions are due to the administration of a previous sensitizing dose of the serum. Unlike ordinary serum sickness, they can be anticipated by the demonstration of positive tests to serum.

**Allergic Shock.**—The person in whom allergic shock occurs almost always is one who is "naturally" sensitive to the serum. The person who is naturally sensitive to horse serum is one who is sensitive to horse dander. This fact can be frequently elicited by the history obtained from the patient. He may be aware that being in the vicinity of horses may bring on an attack of rhinitis, coughing or dyspnea. As a person may be clinically sensitive to horse dander without his knowledge, one should inquire whether he has hay fever or asthma, eczema, or similar manifestation of natural sensitiveness. It is also advisable to inquire into a history of allergy in the family.

True, not all people who are clinically sensitive to horse dander are sensitive to serum. It has been shown that horse dander contains two antigens, the dander antigen (A) and a small amount of the serum antigen (B). If one is sensitive to both of the antigens in the dander, A and B, he will be sensitive to serum. If, on the other hand, he is sensitive only to antigen A, serum will not produce any reaction.

Injection of horse serum into a person who is sensitive to horse dander and serum is an extremely serious undertaking. A reaction is practically certain to occur, even if the amount of serum administered is comparatively small. Large quantities of serum are likely to be extremely dangerous and even one or two drops have been known to kill. The reactions are of the "immediate" type, occurring from several minutes to two or three hours following injection. The mildest reactions consist of a suffusion of the face, some urticarial eruption, stuffiness of the nose, sneezing and asthma. In the more severe cases these symptoms may or may not be present but the main manifestations are varying grades of unconsciousness, loss of reflexes and sphincter control. In the most severe reactions there may occur marked distention of the lungs, with cessation of respiration and death within a few minutes.

#### PROPHYLAXIS

These three types of serum reactions have been thus described in order to emphasize the importance of investigating the history and the sensitivity of every patient who is to be given an injection of therapeutic serum.

**History.**—The following are important questions to ask the patient: Is there hay fever, asthma or eczema in the patient's family? Is the patient subject to allergic manifestations, such as hay fever, vasomotor rhinitis, eczema, asthma or drug idiosyncrasies? Has he ever been around horses? If so, does such exposure produce sneezing, blocked nose, itching of the eyes, coughing, wheezing or dyspnea? Has he had a previous serum injection? How long ago? Has he ever had a serum reaction, particularly in the last four or five months?

**Tests for Sensitivity.**—Such tests should be made on every patient in whom serum administration is contemplated. For the purposes of testing, diluted normal horse serum or the diluted immune serum is used. For a preliminary test the serum should be no stronger than 1:100; i. e., one part of serum to 99 parts of physiologic solution of sodium chloride.

The intracutaneous test consists of the injection of a small amount, 0.05 cc. or less, of diluted serum into the epidermis so that a small wheal is raised. A positive reaction consists of an urticarial swelling with central blanching, peripheral erythema and itching. This occurs within five to twenty minutes.

By the ophthalmic test is meant the instillation of one drop of the diluted serum into the conjunctival sac. A positive reaction usually occurs in a few minutes. It consists of slight injection of the conjunctival vessels and itching, if the response is mild; and marked injection with edema of the conjunctiva and lids, if the reaction is severe. The test should be made first with 1:100 serum dilution. Only if it is negative should a 1:10 dilution be tried. In case of a marked conjunctival reaction it is advisable to instill a drop or two of Solution of Epinephrine into the sac. The ophthalmic test is generally considered a more true indication of clinical sensitivity.

The following routine procedure is recommended: If there is no history of allergy (asthma, hay fever) and an intracutaneous test with 1:100 serum is negative, an intracutaneous test with 1:10 serum should be made. If the latter is negative, one should proceed with serum administration.

If there is no history of allergy and an intracutaneous test with 1:1,000 serum is positive, an ophthalmic test with 1:100 dilution should be made. If the latter is negative, serum 1:10 should be instilled into the conjunctiva. If both ophthalmic tests are negative, serum administration is probably safe but accelerated serum sickness may occur. If either ophthalmic test is positive, serum administration is contraindicated, theoretically.

If the patient is known to have allergic symptoms when near horses or a positive skin reaction to horse dander and if the intracutaneous test with 1:100 serum is negative, he should be tested with 1:100 and 1:10 conjunctivally. If the latter tests are negative, serum administration is probably safe.

If the patient is allergic to horse dander and the intracutaneous test with 1:100 serum is positive and the ophthalmic tests with 1:100 and 1:10 serum are negative, it is very questionable whether serum should be administered, if its administration is not a necessity.

If an individual is allergic to horse dander and both the intracutaneous and the ophthalmic tests with 1:100 serum are positive, the administration of horse serum is absolutely contraindicated unless death is almost certain to ensue without its use.

**Dose and Method of Administration.**—For non-allergic persons the rule applies to give the entire necessary dose of antiserum at the earliest possible moment by slow intramuscular injection; and, in critical conditions, intravenously. There is no known method of preventing ordinary serum sickness.

Those who by the history or the sensitivity test are found to be liable to serum sickness because of acquired allergy—those without a positive eye test—should be given “broken dosage,” i. e., the smallest dose of antiserum that is likely to do any good, and this should be repeated at intervals. It should be injected subcutane-

ously very slowly and into an extremity in such a way as to permit immediate stopping of absorption by means of a tourniquet (e. g., the cuff of a sphygmomanometer) in case early untoward manifestations appear. Additional doses of antiserum may then be given at intervals, provided these do not exceed five days, as a greater interval between serum injections is liable to produce or increase allergy.

The congenitally allergic individual, sensitive to horse serum and horse dander—history and/or both intracutaneous and ophthalmic tests positive—must not be given horse serum under any circumstances or in any way.

The recommendation of rapid desensitization by half hourly increasing doses of the serum is not fully justified. Any one who has seen how painstaking and slow is the method of producing merely a very partial “desensitization” or hyposensitization over a period of months cannot possibly conceive of a desensitization in a few hours sufficiently great to allow the administration of several cubic centimeters of serum. Such a dose of antigen constitutes an amount hundreds of times greater than the quantity safely reached with other antigens—such as pollen or horse dander—after several months of treatment. “Rapid desensitization” under these circumstances is practically impossible.

Immune serum from another species to which the patient is not allergic is the only way of securing the benefits of serum therapy for the congenitally allergic person. It is also the most desirable form for the one who has acquired horse serum allergy. Antiserum obtained from cattle may be suitable. Human immune serum has the great advantage of minimum liability to the production of allergic manifestations.

Avoidance of producing horse serum sensitization should also be mentioned under the heading of prophylaxis. Thus, while one should not delay the employment of diphtheria antitoxin in all cases reasonably suggestive of diphtheria, it is bad practice to give diphtheria antitoxin as a routine to every patient who has a sore throat. In immunization for the prevention of disease, horse serum injections should, as far as possible, be avoided.

#### TREATMENT

Whenever therapeutic serum is administered, Solution of Epinephrine should be at hand ready for instant use. At the first sign of any reaction, 1 cc. of it should be given intramuscularly. If the symptoms are extremely urgent 0.2 or 0.3 cc. should be given intravenously, well diluted and very slowly. The epinephrine may be repeated in a few minutes if necessary. In questionable cases, epinephrine may be injected even before the administration of serum.

It is to be remembered that no amount of epinephrine will prevent a reaction in a person who is naturally allergic to horse serum. However, one who has been so unfortunate as to obtain such a reaction should continue to give epinephrine at short intervals. If the patient has survived the first fifteen or twenty minutes of the reaction, his chances for recovery increase as the minutes elapse. It may be wise at that time to combat some of the effects of the shock by means of morphine hypodermically, by caffeine with sodium benzoate, by heat applied to the body, and by hot drinks.

Ephedrine sulfate by mouth has a more prolonged effect. It may be given in doses of 0.04 Gm. every two to four hours as required to maintain the relief obtained from epinephrine. When it fails, epinephrine injection should be repeated as required for comfort.

Calcium may be given by slow intravenous injection of 20 cc. of 10 per cent solution of calcium gluconate. The rate of injection should not exceed 0.5 cc. per minute. This may be supplemented by 10 cc. of 10 per cent solution of calcium gluconate given intramuscularly, and this injection may be repeated every twelve hours until the rash or other symptoms have subsided.

Acetylsalicylic acid (a 0.3 Gm. capsule every two to four hours as required) is often of help in allaying the itching. When the patient is unable to sleep on account of the pruritus, the addition of barbiturate to the ephedrine (which has a tendency to produce insomnia) is indicated. The three agents may be combined as in the accompanying prescription.

#### *Sedative Prescription*

R. Ephedrine sulfate .....	0.50 Gm.
Phenobarbital .....	0.50 Gm.
Acetylsalicylic acid .....	5.00 Gm.

M. and div. into 15 capsules.

Label: One every 2 to 4 hours as required.

The therapy of urticaria (q. v.) may also be brought into requisition in obstinate cases.

For external use the employment of evaporating applications such as calamine lotion with 1 per cent phenol, diluted vinegar, hot sodium bicarbonate solution or diluted alcohol should not be neglected. If the eruption is generalized, the patient may be given a warm alkaline bath (a cup of baking soda to the tub), which should be followed by freely dusting the skin with talcum powder, to which menthol (0.25 per cent) may be added with advantage.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

#### SEXTON BRAND TOMATOES, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned whole peeled tomatoes, packed in juice.

*Manufacture.*—Tomatoes are washed, inspected, scalded, hand peeled, again inspected and hand packed in cans. Cans filled with tomato juice are exhausted, sealed and processed.

*Analysis* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 93.9%, total solids 6.1%, ash 0.53%, fat (ether extract) 0.5%, protein (N  $\times$  6.25) 1.1%, crude fiber 0.30%, carbohydrates other than crude fiber (by difference) 3.9%.

*Calories.*—0.24 per gram; 7 per ounce.

*Claims of Manufacturer.*—Choice quality whole peeled tomatoes packed in juice without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

#### CERTIFIED BRAND PURE VANILLA EXTRACT

*Manufacturer.*—Certified Extracts, Inc., New York.

*Description.*—Vanilla extract containing water, ethyl alcohol, cane sugar and extractive matter of Bourbon Vanilla Beans.

*Manufacture.*—Vanilla beans are chopped and percolated with 55 per cent alcohol for six days and nights. The percolate is drawn off. The beans are washed and are pressed to secure the remaining percolate, which is added to the first liquid.

Water is added to make a definite amount, sugar is dissolved in the extract and the mixture is aged in storage tanks, filtered and bottled.

*Analysis* (submitted by manufacturer).—(In terms of grams per hundred cubic centimeters).—Vanillin 0.29, resins 0.18, ash 0.30, acidity cc. N/10 per 100 cc., 50 cc., alcohol by volume 35 per cent and lead number (Winton) 0.64.

#### (a) DIADEM BRAND GOLDEN TABLE SYRUP

#### (b) DIADEM BRAND WHITE TABLE SYRUP

*Distributor.*—Schnull & Company, Indianapolis.

*Packer.*—The Torbitt & Castleman Company, Inc., Louisville, Ky.

*Description.*—(a) Table syrup; a blend of corn syrup and refiners' syrup—the same as Bob White Brand Fancy Table Syrup Golden (THE JOURNAL, Aug. 3, 1935, p. 369). (b) Table syrup; a blend of corn syrup and sucrose syrup, flavored with vanilla—the same as Bob White Brand Fancy Table Syrup Crystal White (THE JOURNAL, Oct. 19, 1935, p. 1271).

*Claims of Manufacturer.*—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

#### SEXTON BRAND BLUEBERRIES, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned cooked blueberries, packed in juice.

*Manufacture.*—Blueberries are cleaned, mechanically sorted, inspected, cooked and automatically filled into cans. The cans are sealed and washed.

*Analysis* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 88.9%, total solids 11.1%, ash 0.2%, fat (ether extract) 0.4%, protein (N  $\times$  6.25) 0.4%, crude fiber 1.1%, carbohydrates other than crude fiber (by difference) 9.0%.

*Calories.*—0.41 per gram; 12 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

#### FORT HAMILTON BRAND HAWAIIAN PINE- APPLE—CRUSHED AND GEMS

*Distributor.*—E. H. Frechtling Company, Hamilton, Ohio.

*Packer.*—Hawaiian Pineapple Company, San Francisco.

*Description.*—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole canned pineapple (THE JOURNAL, April 8, 1933, p. 1106).

#### JENNY LEE BRAND MACARONI RINGS AND

#### JENNY LEE BRAND ALPHABETS

*Manufacturer.*—Minnesota Macaroni Company, St. Paul.

*Description.*—Macaroni of various shapes prepared from durum semolina.

*Manufacture.*—The same as for Minnesota Brand macaroni products (THE JOURNAL, Aug. 3, 1935, p. 369).

#### TEXAS GIRL BRAND BAKING POWDER

*Manufacturer.*—The Snow King Baking Powder Company, Cincinnati.

*Description.*—Baking powder consisting of starch, sodium bicarbonate, sodium aluminum sulfate and calcium acid phosphate; the same as Snow King Double Action Baking Powder (THE JOURNAL, Oct. 13, 1934, p. 1151).

#### 18-K BRAND COFFEE

*Manufacturer.*—Winston and Newell Company, Minneapolis.

*Description.*—Roasted coffee; essentially the same as 18-K Brand Vacuum Packed Fresh Roasted Coffee (THE JOURNAL, June 30, 1934, p. 2187) except that it is the whole bean product and is not vacuum packed.

SATURDAY, NOVEMBER 21, 1936

## HYPOGLYCEMIC SHOCK TREATMENT OF SCHIZOPHRENIA

Recently THE JOURNAL made available a report by Glueck<sup>1</sup> of his observations on a new treatment for schizophrenia. A report just released by the Board of Control for England and Wales, written by Dr. Isabel Wilson,<sup>2</sup> also concerns the present status of hypoglycemic shock treatment of schizophrenia. Present opinion, according to the report, indicates that this treatment should be employed primarily in early cases, but even cases of long duration sometimes show satisfactory results. The treatment consists in giving the patient a series of doses of insulin, as a result of which he falls into a state of hypoglycemia. The injections are continued at frequent intervals until the desired result is obtained. As a rule the first dose is from 15 to 30 units of insulin intramuscularly, given at 7 a. m. without previous ingestion of food. The amount is increased by 5 or 10 units daily until a dose is reached to which the patient reacts with what is known as "insulin shock." The most important symptoms of satisfactory shock are sweating, hunger, bradycardia, epileptiform attacks, low temperature, salivation, mental changes and coma. If it is desired to stop the shock before the patient has gone into coma, it may be readily interrupted by giving the patient from 150 to 200 Gm. of dextrose in tea or water. Dextrose may be administered also by nasal tube or by intravenous injection.

There were three deaths from treatment in Vienna among the first 104 cases, but apparently no further deaths have been recorded there or elsewhere. Other than a possible fatal accident, the effect on the heart, the pancreatic damage and the alterations of sugar metabolism are possibly the most important complications. Dr. Wilson believes that this method of treating schizophrenia is promising. The association between insulin treatment and clinical improvement is occasionally striking, but the degree of response to be expected cannot be prophesied on clinical grounds.

1. Glueck, Bernard: The Hypoglycemic State in the Treatment of Schizophrenia, J. A. M. A. 107:1029 (Sept. 26) 1936.  
2. Wilson, Isabel G. H.: A Study of Hypoglycaemic Shock Treatment in Schizophrenia, Board of Control, H. M. Stationery Office, 1936.

Survey of the various theoretical explanations advanced for the success of this treatment reveals no solid ground of physiologic or pathologic proof, and the real mechanism underlying the symptoms and changes that have been observed remains unknown. Thus, while agreement is still far off, Dr. Wilson believes that the treatment is neither too dangerous nor too unpleasant to exclude it as a means of treating the serious disorder known as schizophrenia. The report recommends, therefore, that hypoglycemic shock therapy should be begun in a public mental hospital in England or Wales, only, however, after careful study of the experiences already gained. Furthermore, treatment should be carried out in an "insulin ward"; one physician should be in charge of all treatment, careful records should be kept, control observations should be made, and treated cases should remain under close observation for several years.

Wortis<sup>3</sup> similarly has recently reviewed the subject. His conclusions differ little from those reported by Wilson, but he believes that the most likely theory explaining the results of insulin shock is that metabolism in the central nervous system is improved directly or indirectly by stimulation of carbohydrate consumption. In the seventy-five cases of schizophrenia reported by him, a total average of 63 per cent of the cases showed remission following treatment. In view of the frequency of spontaneous remissions in this disorder, these results are more suggestive than conclusive.

## FOOD POISONING

Significant bacterial contamination of foods falls into two groups: contamination with specific infectious bacteria such as the typhoid bacillus, and contamination with bacteria that may bring about deleterious changes in the food itself.

The contamination of foods with bacteria derived from human and from certain animal infections, such as tuberculosis and various septic processes, is a familiar public health problem. As regards raw milk, particularly, in which the possibilities of contamination are numerous and multiplication of many bacteria can readily occur, preventive measures, public and private, have long been considered necessary. The almost universal practice in the United States of pasteurizing milk has greatly reduced the food hazards of this type. The recent indorsement by the Certified Milk Producers Association of the pasteurization of certified milk emphasizes the sanitary value of the pasteurizing process. Greater cleanliness in the preparing and serving of raw foods has likewise diminished the danger of food-borne infection.

At present the possibility of bacterial contamination of food with specific pathogens is best dealt with by thorough cooking, by general measures of cleanliness,

3. Wortis, Joseph: On the Response of Schizophrenic Subjects to Hypoglycemic Insulin Shock, J. Nerv. & Ment. Dis. 84:497 (Nov.) 1936.

by careful avoidance of foods derived from sick or unsound animals, and possibly, in certain limited groups, by supervision of food handlers. Routine examination of all food handlers, although advocated by a few sanitarians, is a task of almost insuperable difficulty in the hotels and restaurants of large cities because of the frequent turnover of personnel; as regards the individual housewife or domestic servant, it is quite out of the question.

A well known instance of illness caused by swallowing harmful substances formed in foods by bacterial action is botulism. The high fatality of botulism (80 per cent or more) makes this disease justly dreaded in spite of its relative rarity. The botulism bacilli are widely distributed in soil and grow readily in a variety of foodstuffs under anaerobic conditions such as exist in foods preserved by heat and some other methods. Processes for the destruction of the bacteria of botulism were accurately worked out by commercial canning organizations in the United States about ten years ago, and their general application by the canning industry has been followed by immediate practical success.

Since 1925 there has been no instance of botulism traced to the use of food commercially canned in the United States, although there have been two recent outbreaks of botulism caused by commercially canned food imported from other countries, one from imported canned Italian onions,<sup>1</sup> one from imported canned German sprats.

The chief danger from botulism in this country at present appears to lie in the use of locally grown and home canned foods. Although many attempts have been made by the United States Department of Agriculture and other agencies to foster the use of suitable home canning methods, outbreaks of botulism traceable to the use of imperfectly sterilized home canned foods continue to occur. In 1935 there were twenty-three such outbreaks, with sixty-nine cases and forty-two deaths. K. F. Meyer<sup>2</sup> has succinctly expressed the situation: "Until every farmer's wife has been taught that all vegetables or other nonacid foods home canned by the boiling water or oven process must be thoroughly boiled<sup>3</sup> before they are served, botulism intoxication may be anticipated."

Another type of food poisoning caused by the presence in foods of the products of bacterial action has come to light in recent years.<sup>4</sup> It has been established that certain common bacteria, when given an opportunity of growing in foods under suitable conditions, generate a toxic substance that may cause violent gastro-intestinal symptoms. It has, for example, been definitely shown that staphylococci<sup>5</sup> are able to produce a substance that is poisonous when swallowed

by man and by the monkey. This type of food poisoning has been most commonly observed in hot weather in connection with the use of cream-filled pastries. Several outbreaks have been traced to cream pies, chocolate éclairs and similar pastries, the number of victims in a particular outbreak sometimes mounting into the hundreds. Although the symptoms produced by this toxic substance are sometimes severe, the attacks are rarely, if ever, fatal. Cleanliness of the ingredients and proper attention to the sanitation of the environment and of the personnel engaged in manufacture constitute an important safeguard against this form of food poisoning, since heavy initial seeding is doubtless one of the factors leading to abundant production of the toxic substance. Prompt and constant refrigeration is also an important aid in preventing bacterial multiplication. In some localities official restrictions have been placed on the sale of cream-filled bakery goods in hot weather.

### SELLING SAMPLES

One of the smallest performances of certain tradesmen is the purchase from physicians for resale of the samples sent to them by manufacturers of proprietary medicines. In some of our large cities panhandlers float from office to office, begging such medicines from secretaries, office attendants and others to whom the physician may occasionally turn over such materials for disposal. It would seem almost to be taken for granted that the doctor will keep samples of drugs of established merit and that the materials that drop into the hands of the panhandlers are usually new preparations of which the doctor has no knowledge, or proprietary medicines of little or no established usefulness. Nevertheless the practice seems to yield a few shekels, because it perennially appears on the troubled surface of medical waters. The most recent incident concerns an attempt to develop this business in Florida. Florida physicians received postal cards labeled Riverside Specialty Company, offering to purchase samples sent to them by manufacturing houses. An investigation reveals that the Riverside Specialty Company is really Mr. Leo Weinstein, a New York pharmacist, who recently moved to Florida. On inquiry he stated that about the first of September he mailed to 150 physicians in Jacksonville a form letter offering to purchase samples of drugs. After two months passed, during which time he says he did not receive a single reply, he decided to give up the idea and the Riverside Specialty Company went out of business. Mr. Weinstein says that he is again in the pharmacy business. To the physicians of Jacksonville, as Walter Winchell would say, orchids for the quality of their ideals and of their ethics. To panhandling pharmacists who pinch pennies by peddling sample pills, a fragrant bunch of scallions!!! Lest you do not comprehend, a scallion is an onion which fails to bulb but forms a long neck like a leek.

## TYPHOID IN THE CCC

The Civilian Conservation Corps, now in existence more than three years, has enrolled about 1,400,000 men. They have been scattered throughout the United States in several thousand camps largely in rural areas. While the water for these camps was carefully examined and guarded there were nevertheless abundant opportunities for the drinking of polluted water when the men were leaving camp on pass or on work parties on locations some distance away from the camp water supply. When enrolled, the men were examined physically by U. S. Army medical officers and all of them were given the regular army typhoid vaccine. Lieut. Col. George F. Lull<sup>1</sup> of the medical corps has summarized for the three years the number of cases of typhoid that developed and has pointed out the relation of these cases to the time of completion of the typhoid prophylaxis. In a total enrolment of almost a million and a half men up to the first of this year, there had developed only 237 cases of typhoid, thirty-three of which developed before the inoculations with typhoid vaccine were complete. These thirty-three men therefore had probably been infected before coming to camp. Since all these men had been vaccinated against typhoid, it is interesting to note the similarity of the morbidity rate, the mortality rate per thousand, and the case fatality rate for the three years. The morbidity rate per thousand was 0.32 in 1933, 0.27 in 1934 and 0.26 in 1935. The mortality rate per thousand was 0.02 in 1932 and exactly the same in 1934 and 1935. The case fatality rate was 7.59 per cent for 1933, 7.69 for 1934 and 7.61 for 1935. When these men enrolled in the Civilian Conservation Corps, army officers supervised their clothing, their food and their vaccinations and remained with them in camp, being in charge of practically all their activities except their actual work, which was performed under the direction of experienced woodsmen and foresters. The medical department of the army justly may feel proud of the successful results of their prophylaxis of typhoid in the Civilian Conservation Corps.

## MEASURING SKIN PERMEABILITY

Skin permeability presents several problems of far reaching medical importance. Burgi<sup>1</sup> has recently devised a simple but ingenious method of measuring the permeability of the skin to gaseous substances. His apparatus consists primarily of a glass bell jar to which are attached two glass tubes by means of which volatile substances can be passed through one and out of the other and the loss of gas recorded. This method eliminates the possibility of inhalation of gases and also the necessity for measuring either the accumulation of substances in the blood or their elimination through the urine. It is necessary to apply the glass hemisphere closely to the skin and to seal the contact with petrolatum, wax or gelatin. He found that the absorption of carbon dioxide increases with the concentration of the gas in the apparatus. The results were similar with hydrogen sulfide except that concentrations of more than 0.2 per cent were likely to produce an inflamma-

tory reaction in the skin, which in turn diminishes its permeability. Ammonia penetrated the skin almost as easily as carbon dioxide, but carbon monoxide did not penetrate at all. Sodium or calcium chloride penetrated the skin only with difficulty, and a 10 to 27 per cent solution of sodium chloride was necessary before penetration could occur at all. A group of more toxic substances was tested on the skin of rabbits. It was found impossible to produce chloroform anesthesia in these animals by passing chloroform next to the shaved skin. When tetrachlorethane was used, however, total anesthesia could be produced in from twenty to twenty-five minutes. The author's experiments convinced him that only those narcotic liquids that have a boiling point of more than 80 C. can be made to penetrate the skin in sufficient quantity to produce anesthesia or death in the rabbit. His experiments with the permeability of the skin to mercury were also interesting. Pure mercury in the form of gray mercurial ointment penetrated more easily than mercury ( $\text{HgCl}_2$ ) in the form of ammoniated mercury (white precipitate). Furthermore, mercury bichloride in a 1:1,000 solution penetrated little and in a 1:100 solution not at all.

## HISTIDINE TREATMENT OF PEPTIC ULCER

The use of histidine in the treatment of peptic ulcer is of much current interest. Recently Feldheim<sup>1</sup> reported a comparative study of histidine in the treatment of thirty-two patients with ulcer, six involving the stomach and twenty-six the duodenum. Seven of the patients disappeared during the course of their treatment. In one series consisting of eighteen patients, five of whom had ulcer of the stomach and thirteen ulcer of the duodenum, no treatment (except for limitation of spices) other than histidine was given. The second group consisted of fourteen patients, one with ulcer of the stomach and thirteen with ulcer of the duodenum. Of these, four disappeared. The latter group received the conventional treatment for ulcer, including diet, atropine, alkalis and, in addition, histidine. To each of the patients of both groups a series of twenty intramuscular injections of 4 per cent solution of histidine was given. Each patient thus received 5 cc. every day. After the treatment had been instituted for three or four days, practically all the patients became free from pain, in spite of a usual history of prolonged and intense pain for many months. Of the fifteen patients in the first group who were examined by x-rays forty days after the completion of the course of injections, four showed some improvement in the x-ray appearance of the lesion but eleven showed no change whatever. Of the ten patients in the second group similarly examined, five derived definite benefit from the combined treatment and five showed no change. It was Feldheim's conclusion that, although histidine alone may be extremely effective in relieving the pain of ulcer, it has little ability to cure the underlying process. Combined with more conventional methods of treatment, however, histidine may be regarded as a useful adjunct even though no accurate knowledge exists concerning its mode of action in relieving pain.

## Association News

### RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of the Red, as originally announced. The announcement cards that were sent out when the program was planned for the Red network can be changed simply by substituting the word "Blue" for "Red" where it occurs.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

November 24. Be Thankful. W. W. Bauer, M.D.

December 1. "Smog." W. W. Bauer, M.D.

December 8. Heredity and Disease. Morris Fishbein, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARIZONA

**The Healthmobile.**—The Arizona State Board of Health recently inaugurated a mobile tuberculosis service. The healthmobile was purchased with funds given by the Arizona "Forty and Eight," the American Legion and the U. S. Children's Bureau.

### ARKANSAS

**Society News.**—The Benton County Medical Society was addressed at Rogers recently, among others, by Dr. Raymond T. Smith, Fort Smith, on "Upper Respiratory Affections in Relation to Chronic Pulmonary Disorders."—At a meeting of the Johnson County Medical Society, October 22, the speakers were Drs. Sidney J. Wolfemann, Fort Smith, on "Arrhenomablastoma of the Ovary," and Ralph Bowen, Oklahoma City, "Recent Advances in Allergy."

### CALIFORNIA

**Society News.**—At a meeting of the Alameda County Medical Association in Oakland, November 16, Drs. Lester B. Lawrence and Robert A. Glenn discussed "Spontaneous Subarachnoid Hemorrhage" and "Multiple Primary Carcinomas" respectively.—Drs. Burrell O. Raulston and Clarence J. Berne, Los Angeles, discussed hyperthyroidism before the San Diego County Medical Society, November 10.

**Plague Infection in Fleas.**—According to *Public Health Reports*, plague infection has been proved by guinea-pig inoculation in fleas collected from ground squirrels (*Citellus beecheyi*) in the San Ardos area of Monterey County and from pooled fleas taken from chipmunks (genus *Eutamias*) and ground squirrels (*Citellus beecheyi* and genus *Callospermophilus*) in the Lake Tahoe region. A human case of plague was reported from Monterey County in June of this year, but this is the first evidence of plague in ground squirrels in this county since 1931. The fleas collected near Lake Tahoe were from the region where a human case of plague occurred in July of this year.

**Survey of Relief Cases.**—The Central Medical Bureau of San Francisco and the University of California Medical School collaborated in a survey of 1,000 relief cases to determine why the emergency relief load in the state continues a major problem. The survey revealed that 26.7 per cent of the work relief subjects examined were found physically sound, while 6.5 per cent were found to be unemployable because of disease. For the purpose of the survey the relief subjects were divided into four classifications: The A group embraces the physically sound, the B group the physically frail but organically sound, the C group the ones with demonstrable organic lesions not producing symptoms, while the D group included those with demonstrable lesions which would interfere with normal activities. A percentage of 36.5 was recorded for the persons in the C classification, indicating this group to be in a measure responsible for the persistence of the present relief load, it was stated.

### COLORADO

**Society News.**—Dr. William T. H. Baker, Pueblo, addressed the Arapahoe County Medical Society, meeting with its woman's auxiliary, October 26, on "The Business Side of Medicine."—The Arkansas Valley Medical Association was addressed at Salida, October 24, by Drs. Benjamin E. Konwaler, Pueblo, on "Nontuberculous Diseases of the Lungs"; Kenneth B. Castleton, Salt Lake City, "Surgical Aspects of Carcinoma of the Colon," and Emeric I. Dobos, Denver, "Interpretation of Electrocardiograms."—Among others, Dr. Arthur J. Markley, Denver, addressed the Boulder County Medical Society, October 15, on syphilis control. At a special meeting of the Chaffee County Medical Society in Salida, October 8, Dr. Markley also discussed syphilis and Dr. William T. H. Baker, Pueblo, "The Business Side of Medical Practice."—Dr. Vera H. Jones, Denver, discussed the crippled children's program before a special meeting of the Eastern Colorado Medical Society recently.—The Medical Society of the City and County of Denver was addressed November 3 by Drs. Robert W. Gordon on "Gastro-Intestinal Symptoms of Urinary Tract Disorders"; Gerrit Heusinkveld, obstetrics, and Harry H. Wear, "Use of Mandelic Acid in Urinary Infections."—Dr. Raynor E. Holmes Sr., Canon City, discussed "Herniotomy as Complicated by Latent Gonorrheal Infection" before the Fremont County Medical Society, October 26, in Canon City.—At a meeting of the Pueblo County Medical Society in Pueblo, November 3, Dr. Frederick M. Heller spoke on "Recent Advances in Infectious Diseases."

### CONNECTICUT

**Health Officers Appointed.**—Dr. Thomas C. Hodgson has been named health officer of Berlin to fill the unexpired term of Dr. Matthew H. Griswold, and Dr. Harold T. Oesau has been named acting health officer of the town of Stratford, succeeding the late Dr. DeRuyter Howland. Dr. Frank M. Dunn, New London, has been appointed health officer of Waterford to succeed the late Dr. Ross E. Black.

**New Director of Mental Hygiene.**—Dr. George K. Pratt, since 1930 medical director of the mental hygiene committee of the New York State Charities Aid Association, has been appointed to a similar position with the Connecticut Society for Mental Hygiene. He succeeds Dr. Edgar Van Norman Emery, who has been appointed professor of social psychiatry at Washington University School of Medicine, St. Louis. Dr. Pratt graduated from the Detroit College of Medicine and Surgery in 1915. He was the medical director of the Massachusetts Society for Mental Hygiene from 1921 to 1925 and is the author of several books on his specialty.

### DISTRICT OF COLUMBIA

**Personal.**—Dr. Arthur C. Christic, Washington, D. C., will deliver the Silvanus Thompson Lecture before the British Institute of Radiology at its annual congress in Westminster, December 2.—Dr. Jefferson R. Kean, brigadier general, retired, U. S. Army, and founder of Cuba's sanitation department in 1899, was awarded the grand cross of the Order of Carlos Finlay, the highest official honor in Cuba in the medical field.

### GEORGIA

**Officers of State Board.**—Dr. Jesse L. Howell, Atlanta, was elected president of the Georgia State Board of Medical Examiners at a meeting, October 13-14, and Dr. Donald T. Rankin, Alto, vice president. Dr. Miller T. Harrison, Atlanta, is secretary of the board.

**Personal.**—Dr. Warren Bond Matthews, formerly instructor in pathology, Northwestern University School of Medicine, Chicago, has been appointed associate professor of pathology at Emory University School of Medicine, Atlanta, succeeding Dr. Jack C. Norris, who resigned to engage in the private practice of medicine. Dr. Norris will continue to give the course in public health.

## ILLINOIS

**Antirabies Serum on State Free List.**—Antirabies serum will hereafter be distributed without charge to all persons in need of it, the *Chicago Tribune* reported November 14. Certificates of poverty will no longer be required, it was stated, because the state department of health has placed the serum on the state's free list.

**Conference of Health Officers.**—The Conference of Illinois Health Officers and Public Health Nurses will be held at the Auditorium, Springfield, December 8-9. The program will include the following speakers:

Dr. Edward G. Huber, instructor in preventive medicine and hygiene, Harvard School of Public Health, Boston, Administrative Functions of a Health Officer.

Philip Jay, D.D.S., University of Michigan School of Dentistry, Ann Arbor, Dental Caries, A Public Health Problem.

Dr. Kenneth F. Maxcy, director, School of Public Health, University of Minnesota, Minneapolis, Administrative Problems in Contagious Disease Control.

Elmer V. McCollum, Ph.D., professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Diet in Resistance to Disease.

Dr. Raymond A. Vonderlehr, assistant surgeon general, U. S. Public Health Service, Washington, The Problem of Syphilis Control.

Dr. Reginald M. Atwater, executive secretary, American Public Health Association, New York, What Next?

At a luncheon for health officers Wednesday, special public health problems in Illinois will be discussed by Dr. Lloyd L. Arnold, professor of bacteriology and public health, University of Illinois College of Medicine, Chicago; Dr. Winston H. Tucker, Springfield, coordinating epidemiologist, state department of public health; Dr. Milton H. Kronenberg, Chicago, medical director, division of industrial hygiene, state department of public health, and W. H. Haskell, milk sanitarian, U. S. Public Health Service.

## Chicago

**Symposium on Mental Hygiene.**—A public symposium on mental hygiene and the environment was held at the Hotel Bismarck, November 18, by the Illinois Society for Mental Hygiene, with the following speakers:

W. Lloyd Warner, A.E., assistant professor of anthropology and sociology, University of Chicago, Social Anthropology.

Clifford R. Shaw, M.A., director, department of sociology, Institute for Juvenile Research, Sociology.

Dr. Franz Alexander, director, Institute for Psychoanalysis, Psychoanalysis.

Dr. H. Douglas Singer, director, University of Illinois Psychiatric Institute, Social Psychiatry.

**Society News.**—The Chicago Pediatric Society was addressed November 17 by Drs. Katsuji Kato, Chicago, and Robert Blessing, Evanston, Ill., on "Sternal Marrow Puncture in Infants and Children" and "The Incidence of Breast Feeding in Private Practice in a Suburban Metropolitan Area"; these were inaugural theses.—Among others, Dr. Theodora Wheeler discussed "Carbohydrate Metabolism and the Convulsive Threshold" before the Chicago Neurological Society, November 19.—At a meeting of the McDonagh Society for Clinical Research, November 20, Dr. Florimond J. Leblanc spoke on "Pneumonia, Pulmonary Thrombosis and Pulmonary Edema."—The Chicago Society of Industrial Medicine and Surgery was addressed, November 23, by Drs. James J. Callahan on "Fractures Around the Elbow Joint" and Edwin M. Miller, "Fractures Around the Elbow Joint in Children."

## INDIANA

**Society News.**—The Hendricks County Medical Society was addressed in Danville, October 22, by Drs. Oscar T. Scamahorn, Pittsboro, and Marjorie G. E. Morrison, Danville, on "Septic Disease of Knee Joint and Medical History."—Dr. Penn-Gaskell Skillern, South Bend, discussed problems in surgical diagnosis and treatment before the St. Joseph County Medical Society, October 25.—At a meeting of the Jasper-Newton County Medical Society in Rensselaer, October 29, Dr. Roy R. Grinker, Chicago, spoke on infection of the central nervous system.—Dr. Parvin M. Davis discussed injuries to the spine and their treatment before the Floyd County Medical Society in New Albany, October 9.—Dr. Frank H. Jett,

Terre Haute, addressed the Gibson County Medical Society in Princeton, October 12, on industrial surgery.—Dr. John R. Brayton, Indianapolis, addressed the Lawrence County Medical Society, October 14, on "Differential Diagnosis of Syphilis and Other Common Skin Diseases."—Dr. A. Jerome Sparks will discuss "The Management of Urinary Calculi" before the Fort Wayne Medical Society, December 1; Dr. Walter C. Alvarez, Rochester, Minn., addressed the society, November 10, on "Helpful Hints in Diagnosing Puzzling Types of Indigestion."—At a meeting of the Academy of Medicine and Surgery in Fort Wayne, November 17, Dr. Metodi Velkoff spoke on blood counts.—The Indiana Pediatric Society met in Fort Wayne, November 6-7. Dr. Paul L. Schroeder, Chicago, discussed "Delinquency in Children," and John H. Mynskens, Sc.D., Ann Arbor, Mich., "Fractional Speech."—At the Indiana State Conference on Social Work in Indianapolis, November 30-December 1, Dr. Oscar B. Markey, Cleveland, among others, will speak on "Problems of the Adolescent."

## IOWA

**Personal.**—Dr. John H. Peck, Des Moines, has been appointed superintendent of the State Sanatorium for Tuberculosis, Oakdale, succeeding the late Dr. James A. Edwards.—Dr. William O. Purdy, Des Moines, has been appointed assistant medical director of the Equitable Life Insurance Company of Iowa.

**Lectures on First Aid.**—Lectures and demonstrations on first aid, as outlined in the Red Cross course of instruction, were given by members of the Shelby County Medical Society during September and October. The meetings were held each Wednesday evening and were open to the public, the only cost for the course being 60 cents for the purchase of a textbook. The subjects discussed were physiology and bandaging, shocks and wounds and their treatment, artificial respiration and its uses, burns and scalds and their treatment, effects of heat and cold and treatment, fractures, poisons, unconsciousness and treatment of common emergencies, and transportation of the sick and injured.

**Second Annual Diphtheria Drive.**—The second annual campaign to eradicate diphtheria from Polk County was recently launched by the Des Moines Academy of Medicine and the Polk County Medical Society in cooperation with the city health department, the public health nursing association and the school nursing bureau. The goal in this campaign is to immunize two thirds of the 3,000 infants born in the county every year. To this end a number of physicians agreed to inoculate for one dollar every child between the ages of 6 months and 2 years who is brought to their offices Saturday mornings from 11 to 12 o'clock on October 31, November 7, 14, 21 and 28, the state journal announces. Pamphlets on the early immunization of children in the preschool age group have been circulated among the parents. The journal points out that 599 cases of diphtheria were reported in Iowa during 1935, while 287 were recorded from January through October of this year. In 1935 the number of deaths from this cause was fifty-six, while sixteen were recorded from January through August of this year. The immunization of children against diphtheria is a feature of Iowa's program under social security activities. The work, under the direction of the state department of health, has been completed in seventeen counties with a total of 6,989 children immunized. In Audubon, Crawford, Hancock, Harrison, Winnebago and Woodbury counties, where the work is nearing completion, 2,930 children have been immunized.

## KENTUCKY

**District Meeting.**—The Fifth District Medical Society will meet in Louisville, November 24, with the following speakers: Drs. Edward K. Martin, Frankfort, on "Extra-Uterine Pregnancy"; Philip F. Barbour, Louisville, "Acute Appendicitis in Children"; Frederick G. Speidel, Louisville, "Coronary Occlusion," and James Duffy Hancock, Louisville, "Diagnosis and Management of Acute Gallbladder Disease."

**Society News.**—Drs. Eslic Asbury, Cincinnati, and Francis M. Massie, Lexington, addressed the Licking Valley Medical Association in Cynthia in September on sciatica and surgical shock, respectively.—At a meeting of the Jefferson County Medical Society, Louisville, November 16, the speakers were Drs. Richard Douglas Sanders, on "Cyclopropane Anesthesia"; Pat R. Imes, "Recent Advances in the Treatment of Varicose Veins and Leg Ulcers," and Robert F. Monroe, "Seasonal Variation in the Incidence of Puerperal Infection."—Hamp-

den C. Lawson, Ph.D., assistant professor of physiology, University of Louisville School of Medicine, addressed the Louisville Obstetrical and Gynecological Society, November 23, on "Physiology of the Endocrine Glands."

### MARYLAND

**Fund for the Study of Infantile Paralysis.**—About \$350,000 will be given to Johns Hopkins University School of Medicine, Baltimore, to be used in seeking a cure for infantile paralysis, under the will of the late Mrs. M. B. Graham, Washington, D. C.

### MASSACHUSETTS

**Special Service for Physicians.**—A special service for physicians and medical students was held in the Cathedral Church of St. Paul, Boston, October 18. Dr. John M. T. Finney, professor emeritus of surgery, Johns Hopkins University School of Medicine, Baltimore, the principal speaker, spoke on "Religion in Medicine."

**Dr. Fitz Appointed Lecturer in History of Medicine at Harvard.**—Dr. Reginald Fitz, Wade professor of medicine, Boston University School of Medicine, and director of Evans Memorial Hospital, has been appointed lecturer in the history of medicine at Harvard University Medical School for three years. Dr. Fitz, who is university marshal at Harvard, resigned in 1935 as associate professor of medicine at the medical school to go to Boston University.

**Scholarships at Harvard.**—Prize scholarships have been made available in the Harvard University Medical School, Boston, through gifts made recently by Mr. Edward S. Harkness and Dr. Daniel F. Jones. One or two will be awarded to persons entering the freshman class in 1937. Since the scholarships will be open to all students whatever their financial circumstances, the stipend will vary from \$100 to \$1,000, depending on the financial resources of the recipient. Holders of the scholarships who maintain, during their first year, a high honor record will continue to hold them throughout the medical school course.

**Personal.**—Dr. John J. Poutas, Newton, assistant director of communicable diseases in the state department of health since 1934, has been appointed health officer for the Connecticut River Valley District to succeed the late Dr. Harold E. Miner, Holyoke. The gold medal of the American Roentgen Ray Society for the outstanding exhibit at its annual meeting was awarded to Drs. Aubrey O. Hampton and Jacob Maurice Robinson, Boston. Their exhibit was entitled "The Iodized Oil Demonstration of Rupture of the Intervertebral Disk into the Spinal Canal with Special Reference to Unilateral Lumbar Lesions Accompanied by Low Back Pain with Sciatic Radiation."

**Medical Historical Pageant.**—The Boston Medical History Club presented a medical historical pageant at the Boston Medical Library, November 16. The characters of the following were portrayed by students of Tufts College Medical School:

#### Founding of Medical Schools

John Morgan, 1735-1789.  
Benjamin Rush, 1745-1813.  
Daniel Drake, 1785-1852.

#### Surgery

Philip Syng Physick, 1768-1837.  
Valentine Mott, 1785-1865.  
Joseph O'Dwyer, 1841-1898.

#### Experimental Medicine

William Beaumont, 1785-1853.  
Alexis St. Martin.

#### The New Humanity

Marie Elizabeth Zakrzewska, 1829-1902.  
Linda Richards, 1840-1911.

#### Preventive Medicine

Walter Reed, 1851-1902.  
William Crawford Gorgas, 1854-1920.

### MICHIGAN

**Highland Park Physicians' Club.**—The eleventh annual clinic of the Highland Park Physicians' Club will be held at the Highland Park General Hospital, December 2. The following program will be presented:

Dr. James E. Davis, Detroit, Malignant Lesions of the Cervix Uteri.  
Dr. Arthur J. Bedell, Albany, N. Y., General Vascular Lesions as Seen in the Fundus.

Dr. Frederick F. Tisdall, Toronto, Ont., Canada, The Mineral and Vitamin Requirements of the Child.

Dr. Charles Anderson Aldrich, Winnetka, Ill., Clinical Observations on Grip.

Dr. Louis J. Harris, Toronto, Indications for Cesarean Section.

Dr. Herman L. Kreisner, Chicago, Treatment of Bladder Neck Obstruction by Transurethral Resection.

Dr. Dean D. Lewis, Baltimore, Acute Pancreatitis.

Dr. George W. Crile, Cleveland, The Thyroid Gland.

Dr. George M. Curtis, Columbus, Iodine as Related to Thyroid Disease.

Joseph M. Hackett, mayor of Highland Park, will give the address of welcome at the banquet in the evening at the Book Cadillac Hotel and Dr. Crile will discuss his recent African expedition.

**Society News.**—The first annual banquet of the Grand Rapids Society for the Hard of Hearing, October 27, celebrating National Hearing Week, was addressed, among others, by Dr. Austin A. Hayden, Chicago, on "The Conservation of Hearing." A motion picture entitled "The Social Agencies of the Grand Rapids Community Chest" was shown.—Dr. Clyde K. Hasley, Detroit, discussed "Treatment of Malignancies of the Skin and Mucous Membranes" before the Calhoun County Medical Society in Battle Creek, November 3.—Dr. George M. Curtis, Columbus, Ohio, addressed the Academy of Surgery of Detroit, November 12, on "Experimental Studies—Stomach Motility as Related to Gastro-Intestinal Diseases."—Dr. Frederick B. Burke, Detroit, addressed the Ionia-Montcalm Counties Medical Society at Ionia, October 13, on the basic science law.—At a meeting of the Detroit Pediatric Society, November 4, Dr. Louis H. Newburgh, Ann Arbor, spoke on "The Overweight Child."—Dr. John A. Hookey, Detroit, discussed "Treatment of Eczema" before the Lenawee County Medical Society, October 20.

**Public Health Meeting.**—The sixteenth annual Michigan Public Health Conference was held in Lansing, November 11-13, with Dr. Clyde C. Slemons, state health commissioner, presiding. The following program was presented:

Dr. Thomas Farran, surgeon general, U. S. Public Health Service, Washington, D. C., Syphilis as a Public Health Problem.

Dr. Clara M. Davis, Winnetka, Ill., Science and Common Sense in the Feeding of Children.

Dr. James D. Bruce, Ann Arbor, The Michigan Program for Professional and Public Health Education.

Dr. Carl V. Weller, Ann Arbor, Cancer.

Lon W. Morrey, D.D.S., director, bureau of public relations, American Dental Association, Chicago, Mouth Hygiene.

Leslie C. Frank, sanitary engineer in charge, office of milk investigations, U. S. Public Health Service, Washington, D. C., Milk Control.

Dr. Carey P. McCord, director, bureau of industrial hygiene, Detroit Department of Health, Industrial Hygiene.

One evening session was addressed by Dr. Farran on "Future Trends in Public Health" and another by Joseph R. Hayden, Ph.D., professor of political science, University of Michigan, "The Philippines in Transition." The meeting concluded with a symposium on communicable disease Friday morning.

### MINNESOTA

**Outbreak of Diphtheria.**—Twenty-nine cases of diphtheria with five deaths were reported in an outbreak in Minneapolis between October 1 and October 25, according to the newspapers. Only about 15 per cent of the city's school children were immunized against the disease at the time of this report, but plans were being made to launch an antidiphtheria campaign.

**Society News.**—Dr. Theodore Diller, Pittsburgh, gave a lecture at the Mayo Clinic, Rochester, October 22, on "Human Credulity as Illustrated by Witchcraft."—The Stearns-Benton Counties Medical Society was addressed, October 22, among others, by Drs. Alfred W. Adson, Rochester, diagnosis and treatment of trigeminal neuralgia, and Charles E. Wright, of the American Medical Association; Trustee of the Association.

**Public Health Meeting.**—At the annual dinner of the Minnesota Public Health Association in Minneapolis, November 13, Dr. Horton R. Casparis, professor of pediatrics, Vanderbilt University School of Medicine, Nashville, was the guest speaker. Dr. Charles H. Mayo, Rochester, president of the association, was toastmaster. Other speakers included Dr. Caroline Hedger, Elizabeth McCormick Memorial Fund, Chicago, and Miss Frances Brophy, New York, field adviser of the National Tuberculosis Association. A Christmas Seal institute opened the all day session, marking the thirtieth anniversary of the introduction of the seal into the United States. Dr. Olaf J. Hagen, Moorhead, was elected president.

**Ex-Convict Shokunbi Given Suspended Sentence.**—Samuel P. Shokunbi, alias Samuel Kojoe Pearse, pleaded guilty, October 8, to practicing healing without a basic science certificate and was sentenced to sixty days in the St. Paul Workhouse; the sentence was suspended and he was placed on probation for one year. Shokunbi specialized in the sale of an Herb Tonic, a Gall Stone Remover and a Female Regulator, at prices varying from \$2 to \$5 per bottle. The defendant was arrested in May 1927 at St. Louis on a suspicion of robbery, and in July 1927 he was sentenced under the name of Samuel Kojoe Pearse to four years at hard labor in the penitentiary at Leavenworth. This sentence was imposed in the U. S. District Court at St. Louis, for using the mails to defraud in connection with the sale of medicine. He served twenty-seven months at Leavenworth and was released.

## MISSISSIPPI

**Society News.**—At a meeting of the Delta Medical Society in Belzoni, October 14, the speakers included Drs. Bernard H. Booth of Drew, on "The Common Cold and Its Treatment," and Henry King Wade, Hot Springs National Park, Ark., "Gonorrheal Epididymitis and Its Treatment."—The November meeting of the Central Medical Society will be addressed by Drs. Laurance J. Clark, Vicksburg, on pneumonia, and George W. F. Rembert, Jackson, coronary thrombosis.

## NEW YORK

**Personal.**—Dr. Frank Reynolds, Syracuse, was honored at a testimonial dinner October 15 on his retirement from the staff of the Crouse-Ingving Hospital, with which he has been associated since its founding in 1912.—Dr. Samuel W. Hamilton, White Plains, assistant medical director of the New York Hospital, Westchester Division, has resigned to become director of a hospital survey for the National Committee for Mental Hygiene. Dr. James H. Wall, a member of the hospital staff since 1928, has succeeded Dr. Hamilton.

**Cancer Crusade Week.**—The governor proclaimed the week of November 1-7 as Cancer Crusade Week. The proclamation directed attention to the 18,000 deaths from cancer annually in New York and urged cooperation of all agencies to encourage early diagnosis and treatment. A cancer committee pointed out that New York has been a pioneer in the fight against cancer, having had the first special cancer hospital in the United States, the first free home for incurable cancer patients, the first state cancer institute, the first municipal cancer hospital, the first self-supporting cancer educational committees, the first rural diagnostic and treatment cancer clinic, the first national cancer fighting organization, the first international conference on cancer control, at Lake Mohonk in 1926, and publication of the first medical journal devoted to all aspects of the disease.

**Society News.**—Dr. Frederick S. Wetherell, Syracuse, addressed the Otsego County Medical Society, October 14, in Cooperstown, on "Surgery of the Sympathetic System as Related to the Problems of General Practice."—Dr. Israel S. Wechsler, New York, addressed the Medical Society of the County of Rockland at Letchworth Village, Thiells, October 14, on "Neuritis: Etiology and Management."—At a meeting of the Dutchess County Medical Society in Poughkeepsie, October 14, Dr. Maximilian A. Ramirez, New York, discussed allergy. Dr. Russell L. Cecil, New York, addressed the Niagara County Medical Society, October 13, on pneumonia.—Drs. Charles H. Baldwin and Joseph J. Witt, Utica, addressed the Oneida County Medical Society, October 13, at Broadacres Sanatorium, on "Tuberculosis of the Bones and Joints" and "Tuberculosis in Children" respectively.—Dr. Silas J. Banker, Fort Edward, recently resigned as secretary of the Washington County Medical Society after thirty years of service. Dr. Denver M. Vickers, Cambridge, succeeded him.

## New York City

**Hospital News.**—Dr. Bernhard Dattner, Vienna, lectured at Mount Sinai Hospital, October 7, on "Nervous Manifestations of Alimentary Hypersensitivity."—Dr. Robert E. Pound has been appointed director of the department of roentgenology of the Misericordia Hospital.

**District Meeting.**—The First District Branch of the Medical Society of the State of New York held its annual meeting at Morrisania Hospital, October 7. Among the speakers were Drs. Clarence H. Smith, on "Unique Methods of Tonsillectomy"; Frederick W. Williams and Thomas J. O'Kane, "Surgical Diabetes," and William Klein, "Treatment of Fracture of Femur."

**Academy of Medicine Election.**—Dr. James Alexander Miller, professor of clinical medicine, College of Physicians and Surgeons, Columbia University, has been chosen president of the New York Academy of Medicine for a term of two years; Dr. Arthur F. Chace, vice president for three years, and Dr. Lewis F. Frissell, recording secretary for three years. Dr. Miller will succeed Dr. Eugene H. Pool.

**Dr. Flexner to Teach at Oxford.**—Dr. Simon Flexner, director emeritus of the Rockefeller Institute for Medical Research, has been appointed Eastman visiting professor at Oxford University, Oxford, England, for the academic year 1937-1938. The Eastman professorship was founded by the late George Eastman of Rochester to provide for scholars in American universities to go to Oxford as visiting professors for terms of from one to five years.

**Friday Afternoon Lectures at the Academy.**—Dr. Hayes E. Martin delivered the third lecture of the Friday afternoon series at the New York Academy of Medicine, November 20, on "The Curability of Cancer of the Tongue by Modern Therapeutic Methods." Following is the list of lectures for December and January:

Dr. John Douglas, December 4, Acute Inflammation of the Gallbladder and the Biliary Ducts.  
Dr. Arthur C. McGraft, December 11, Rational Symptomatic Drug Therapy.  
Dr. Adolph G. G. DeSanctis, December 18, Common Gastro-Intestinal Diseases of Infants and Children.  
Dr. Percy S. Pelouze, Philadelphia, January 8, Gonorrhea in the Male and Its Treatment.  
Dr. Readie Garfield Snyder, January 15, Recent Advances in the Treatment of Chronic Arthritis.  
Dr. David P. Barr, St. Louis, January 22, Recent Advances in the Endocrine Field.  
Dr. Bernard S. Oppenheimer, January 29, Angina Pectoris and Coronary Artery Disease.

**Society News.**—Drs. Henry S. Dunning and Harold G. Wolff addressed the New York Neurological Society and the section of neurology and psychiatry of the New York Academy of Medicine, November 10, on "The Relation Between Function and Vascularity in the Nervous System" and Dr. Eugene Bernstein, on "The Emotional Factor in Skin Disorders." Dr. William W. Herrick delivered the first Friday afternoon lecture of the academy's series, November 6, on "Early Diagnosis and Treatment of Hypertensive Cardiovascular Disease"; the second was given by Dr. Martin E. Rehfuss, Philadelphia, November 13, on "The Gallbladder Problem."—Dr. Allen K. Krause, Baltimore, addressed the Brooklyn Thoracic Society, October 16, on "Modern Management of Clinical Tuberculosis."—Dr. Jerome P. Webster addressed the New York Surgical Society, October 28, on "Application of Principles of Plastic Surgery in General Surgery."—Drs. Hugo Roesler, Philadelphia, and Dana W. Atchley addressed the Medical Society of the County of Kings, October 20, on "Selected Topics Related to the Roentgenology of the Cardiovascular System" and "Nephrosis with Special Reference to Its Clinical Characteristics, Progress and Treatment" respectively.—Dr. Frank H. Lahey, Boston, addressed the Harlem Medical Association, November 4, on "Thyroid Disease and Hyperparathyroidism." Discussion was opened by Drs. Charles Gordon Heyd, President, American Medical Association; William Barclay Parsons and Henry W. Louria.—Dr. Benjamin Wallace Hamilton has been appointed secretary of the Medical Society of the County of New York to fill the unexpired term of the late Dr. Daniel S. Dougherty.

## NORTH CAROLINA

**Hospital News.**—A graduate course in pulmonary diseases was presented at Lincoln Hospital, Durham, October 15-16, by the North Carolina State Department of Education, Duke University, Durham, and the University of North Carolina, Chapel Hill.

**District Meeting.**—The Fifth District Medical Society held a meeting at Sanatorium, October 29, at which Dr. Irvin Stein, Philadelphia, was the guest speaker, on "Bone Metabolism." Others on the program were Drs. James W. Tankersley, Greensboro, on "Cancer of the Breast"; Verne S. Caviness, Raleigh, "Heart Pain"; Robert F. Leimbach, Charlotte, "Nervous Indigestion," and John N. Robertson, Fayetteville, "The Common Cold." Dr. Charles F. Strosnider, Goldsboro, president of the Medical Society of North Carolina, made an address at the dinner.

**Personal.**—Dr. Harry L. Brockmann, High Point, was elected chief of staff of the Burrus Memorial Hospital to succeed the late Dr. John T. Burrus.—Dr. Paul P. McCain, medical director and superintendent of the North Carolina Sanatorium for the Treatment of Tuberculosis, has been appointed manager of a new state sanatorium now under construction at Black Mountain, ten miles from Asheville. Dr. McCain will have charge of both institutions, with assistant managers who will be appointed later, it was said. It is expected that a part of the new hospital will be finished by April 1937.

**Society News.**—The Tenth District Medical Society held its fall meeting at Asheville, September 23. The speakers included Drs. James K. Hall, Richmond, Va., on "Guilt and Punishment"; James P. Rousseau, Winston-Salem, "Value of Radiation Treatment of Benign Lesions of the Female Pelvis," and Jake G. Woodward, Asheville, "Treatment of Early Syphilis."—Drs. James D. Whaley, Hickory, and Samuel M. Bittinger, Sanatorium, addressed the Catawba Valley Medical Society, Lincolnton, November 10, on diagnosis and treatment of genito-urinary tuberculosis and adult pulmonary tuberculosis,

respectively. —The Southeastern Branch of the American Urological Association is to be held in Charlotte, December 4-5. Dr. Hamilton W. McKay, Charlotte, is president-elect of the branch.

### OHIO

**Graduate Program at Toledo.**—The Medical Institute of the University of Toledo presented its third annual "Post-graduate Day Program" November 6. The guest lecturers were Drs. Otto H. Schwarz and David P. Barr, St. Louis, who spoke on obstetrics and endocrinology, respectively. The program is made possible through a bequest of the board of trustees of the old Toledo Medical College.

**Health Commissioners' Meeting.**—The seventeenth annual conference of Ohio health commissioners with the state health department was held in Columbus November 4-6. Among the speakers were Drs. Raymond A. Vonderlehr, U. S. Public Health Service, on syphilis; Arthur J. Skeel, Cleveland, essentials of good maternal care, and George M. Lyon, Huntington, W. Va., the school health program as part of the community health program. At a luncheon meeting Thursday November 5 the speakers were Drs. Wilson G. Smillie, Boston, on influenza, and John H. J. Upham, Columbus, President-Elect of the American Medical Association.

**Society News.**—Dr. Jacob Victor Greenbaum, Cincinnati, addressed the Clinton County Medical Society, Wilmington, October 13, on "Preventive Procedures in Infancy." —Dr. Thomas P. Sharkey, Dayton, spoke on insulin protamine in treatment of diabetes mellitus at a meeting of the Darke County Medical Society, Greenville, October 16. —Dr. George I. Nelson, Columbus, discussed cardiovascular diseases before the Hardin County Medical Society at Kenton, October 15. —Dr. Harry E. Le Fever, Columbus, addressed the Hempstead Academy of Medicine, Portsmouth, October 12, on "Common Lesions of the Spinal Cord." —Dr. Louis J. Roth, Columbus, addressed the Morrow County Medical Society, Mount Gilead, October 13, on treatment of syphilis and gonorrhea.

### OKLAHOMA

**Clinical Conference.**—The seventh annual conference of the Oklahoma City Clinical Society was held October 26-29 at the Biltmore Hotel, Oklahoma City. The guest speakers were Drs. Charles Gordon Heyd, New York, President of the American Medical Association, and Webb W. Weeks, New York; Tracy B. Mallory, Boston; George R. Livermore and Willis C. Campbell, Memphis; Hans Lissner, San Francisco; Francis E. Seneor and Sumner L. S. Koch, Chicago; James R. McCord, Atlanta, Ga.; Tinsley R. Harrison, Nashville, Tenn.; Waltman Walters, Rochester, Minn.; Charles L. Brown, Philadelphia; Willard R. Cooke, Galveston, Texas; Albert C. Furstenberg, Ann Arbor, Mich.; Wilburt C. Davison, Durham, N. C., and Karl A. Menninger, Topeka, Kan.

### PENNSYLVANIA

**Society News.**—Dr. Ross K. Childerhose, Allenwood, addressed the Lebanon County Medical Society, November 10, on early diagnosis of tuberculosis. —Drs. Eldridge L. Eliason and Lawrence Curtis, Philadelphia, were the guest speakers at the fall clinic of the Lycoming County Medical Society, Williamsport, November 13. Both conducted clinics in the morning; in the afternoon Dr. Eliason spoke on "Deformity in Fracture Results" and Dr. Curtis on "Treatment of Facial Injuries."

#### Philadelphia

**Innovation in Programs for Branch Societies.**—The program committee of the Philadelphia County Medical Society instituted a new plan for meetings of branch societies with a symposium on the diagnosis of syphilis, which was presented in turn before each branch. The speakers were Drs. Jefferson H. Clark, on laboratory aspects; Sigmund S. Greenbaum, lesions of the skin and mucous membranes; William Egbert Robertson, cardiovascular syphilis, and Michael A. Burns, syphilis of the nervous system.

**Society News.**—Drs. Edward T. Crossan and Robert R. Layton Jr., among others, addressed the Philadelphia Academy of Surgery, November 2, on "The Fay Cast in the Treatment of Fracture of the Neck of the Femur." —Drs. Alexander Spencer Kaufman and Irvin Feldman were among the speakers who addressed the Philadelphia Laryngological Society, November 3, on "Intratympanic Thyroxine Injections in Chronic Catarrhal Deafness." —A symposium on the use of analgesia and anesthesia in obstetrics was presented at a meeting of the Obstetrical Society of Philadelphia, November 5. Dr. Charles

M. M. Gruber gave a paper on "Pharmacologic Actions of the Newer Barbituric Acid Compounds," which was discussed by Drs. Henry S. Ruth, Lida Stewart Cogill, Jesse O. Arnold, Thaddeus L. Montgomery, Philip F. Williams, Clifford B. Lull and Edward A. Schumann. Dr. Pascal Brooke Bland described visits to European clinics. —A symposium on psychiatry and the criminal insane was presented at a meeting of the Philadelphia Psychiatric Society, November 13, by Drs. Charles A. Zeller, Waymart, and Philip Q. Roche.

### Pittsburgh

**Society News.**—A symposium on infantile paralysis was presented at a meeting of the Pittsburgh Academy of Medicine, November 10, by Drs. Howard H. Permar, Henry T. Price and David Silver. —Drs. William W. Briant Jr., Mount Lebanon, and Paul J. McGuire, Homestead, addressed the Pittsburgh Pediatric Society, November 13, on "Some Extra-genital Effects of Ureteral Obstruction" and "Primary Pulmonary Tuberculosis and the Tuberculin Test" respectively. Dr. Alfred S. McElroy reported a case of acute hemorrhage from the throat.

**District Meeting on Syphilis.**—The Tenth Councilor District of the Medical Society of the State of Pennsylvania met in Pittsburgh November 18 with a program devoted to syphilis. Dr. William H. Guy and his associates gave clinical demonstrations at the Falk Clinic in the morning. After a luncheon at the Hotel Schenley the following program was presented:

Dr. William H. Guy, Modern Treatment of Various Stages of Syphilis.  
Dr. Frederick B. Utley, Importance of Recognition and Treatment of Cardiovascular and Visceral Syphilis.

Dr. George J. Wright, Manifestations, Sequelae and Treatment of Syphilis of the Nervous System.

Dr. Edgar S. Everbari, Harrisburg, The Part That Can Be Played by the Physician to Stop the Spread of Syphilis.

At a public meeting at the Schenley in the evening, Dr. Guy showed slides of syphilis; Dr. Cornelius C. Wholey spoke on "Mental Conditions and Social Problems Caused by Syphilis," and Dr. Allan J. McLaughlin, U. S. Public Health Service, Washington, D. C., "The Part That Can Be Played by the Public to Stamp Out Syphilis."

### TENNESSEE

**Health at Memphis.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million indicate that the highest mortality rate (23.8) appeared for Memphis and that the rate for the group of cities was 11.6. The mortality rate for Memphis for the corresponding week of 1935 was 16.7 and that for the group of cities was 10.8. The annual rate for the eighty-six cities for the forty-five weeks of 1936 was 12.1, as compared with a rate of 11.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

### WASHINGTON

**Hospital News.**—Providence Hospital, Seattle, celebrated its twenty-fifth anniversary recently. Three physicians who served on the original reception committee were present at the jubilee: Drs. Philip von Phul, Sherald F. Wilsic and Harry A. Shaw, all of Seattle.

**Society News.**—Drs. Philipp Schonwald and Hale A. Haven addressed the King County Medical Society, Seattle, November 16, on "Atmospheric Causes of Allergic Diseases in Western Washington" and "Operability and Curability of Malignant Tumors Arising from the Brain" respectively. The society was addressed, October 19, by Drs. Paul R. Rollins on "Reduction of Fetal Mortality in Breech Presentations" and Frederick B. Exner, "Benign Tumors of the Stomach."

### WISCONSIN

**University News.**—Marquette University instituted this year a course in medical technology leading to the degree of bachelor of science. The first two years will be spent in the liberal arts college and the last two in practical work in Milwaukee hospitals.

**Society News.**—Drs. Emil Novak, Baltimore, and John W. Smith, Milwaukee, addressed the Medical Society of Milwaukee County, October 14, on "The Cause and Treatment of Functional Uterine Bleeding" and "Acne Vulgaris" respectively. —Dr. Joseph W. Gale, Madison, among others, addressed the Milwaukee Society of Clinical Surgery, October 27, on "Treat-

ment of Suppurative Pleurisy."—Drs. Frank A. Boeckman, Marshfield, and Merritt L. Jones, Wausau, addressed the Wood County Medical Society, Wisconsin Rapids, August 26, on carbon monoxide poisoning and backache, respectively.—Dr. Thomas O. Nuzum, Janesville, addressed the Rock County Medical Society, Beloit, October 27, on "Diagnosis of Encapsulated Pleural Effusions."

**Milwaukee Medical Service Plan.**—The Medical Society of Milwaukee County inaugurated a medical service plan for the budgeting of medical and hospital bills, October 20, with Mr. B. B. McKinsty in charge. Patients will be referred to the service by their own physicians, and details of meeting costs will be worked out to fit the individual income. According to a statement issued by the society, the plan is the result of several years' study of the local situation and of similar plans in other cities. Most of the hospitals in Milwaukee have agreed to cooperate with the service. Members of the committee that worked out the plan are Drs. Dexter H. Witte, chairman; Timothy J. Howard; William J. Houghton, Wauwatosa, and Mr. Theodore Wiprud, executive secretary of the society.

**Physicians Honored.**—Drs. Theodore J. Redelings, Marinette, and Edward Sawbridge, Stephenson, Mich., were guests at a testimonial dinner in Marinette, October 21, honoring them for fifty years of medical service. Dr. Sawbridge has practiced in Menominee County fifty-three years and Dr. Redelings is in his fiftieth year of practice in Marinette. The principal speakers at the dinner were Drs. Ralph M. Carter, Green Bay, past president, and Stephen E. Gavin, Fond du Lac, president of the State Medical Society of Wisconsin. Medals were presented to the two physicians. Dr. John C. Wright, Antigo, was honored at a luncheon given by the Langlade County Medical Society, October 14, marking his retirement from medical practice after fifty-five years. Dr. Wright was for many years secretary of the county society.

### GENERAL

**Examinations in Dermatology and Syphilology.**—The American Board of Dermatology and Syphilology announces that a written examination for Group B applicants will be held in various cities throughout the country April 17, 1937. Oral examinations for Group A and B applicants will be held in Philadelphia, June 7-8, 1937. Dr. C. Guy Lane, 416 Marlborough Street, Boston, is the secretary.

**New Surgical Journal.**—A new publication entitled "Surgery, A Monthly Journal Devoted to the Art and Science of Surgery," will make its appearance January 1. This journal is not to be the official organ of any group or organization. According to the announcement, it is to be a clinical and experimental journal of surgery with a representation in its editorial board and committee on publications of representatives from the field of general surgery and its specialties, as well as the preclinical medical sciences. Dr. Owen H. Wangensteen, professor and head of the department of surgery, University of Minnesota Medical School, Minneapolis, and Dr. Edward W. Alton Oschner, professor and head of the department of surgery, Tulane University of Louisiana School of Medicine, New Orleans, will edit the new publication.

**Clinical and Climatological Society Meeting.**—Dr. James E. Paullin, Atlanta, was elected president of the American Clinical and Climatological Association at its annual meeting at Richmond, Va., October 26-28. Vice presidents elected were Drs. John B. Hawes II, Boston, and Ralph H. Major, Kansas City, Mo., and Dr. Francis M. Rackemann, Boston, was reelected secretary. Speakers at the meeting included:

- Dr. Benjamin M. Baker Jr., Baltimore, The Arthritis of Bacillary Dysentery.
- Dr. Howard F. Root, Boston, Insulin Protamine in Treatment of Diabetes.
- Dr. Frederic M. Hanes, Durham, N. C., Metabolic Studies in Sprue.
- Dr. Edgar Mayer, New York, The Dietary Treatment of Tuberculosis—More Recent Aspects.
- Dr. Lewis J. Moorman, Oklahoma City, Calcification of the Spleen.
- Dr. Alphonse R. Dochez, New York, General Significance of the Etiologic Agents of Upper Respiratory Tract Infection.
- Dr. Roy R. Snowden, Pittsburgh, Treatment of the Thyroid Crisis.
- Dr. Alfred H. W. Caulfeild, Toronto, The Correlation of Specific Sensitization as It Occurs Clinically in Man and as Induced Experimentally in Animals.

The next meeting will be held at Baltimore in October 1937.

**Conference on Hospital Statistics.**—A feature of the meeting of the American Hospital Association in Cleveland was a conference on hospital statistics, attended by representatives of national and regional organizations. An analysis of statistical material obtained from about 1,000 hospitals as to

bed capacity and number of admissions, presented by Dr. Joseph W. Mountin, U. S. Public Health Service, Washington, D. C., revealed the importance of uniform definitions for the hospitals in filling out questionnaires and for the local and national agencies in the preparation of them. It was pointed out that the use of the manual of the American Hospital Association might ultimately reduce the number of independent questionnaires received from different national associations. The group decided to meet in February in Chicago to consider revision of the definitions for adoption by the various representatives at the meeting.

**Thirtieth Annual Sale of Christmas Seals.**—The thirtieth annual sale of Christmas Seals will be launched by the National Tuberculosis Association and its component societies Thanksgiving Day. The first sale was held in Delaware in 1907 by Miss Emily P. Bissell, who raised \$3,000 to use toward building a hospital for children with tuberculosis. The National Tuberculosis Association was formed in 1904 and now has 1,981 affiliated associations. Listing the milestones in the tuberculosis movement, the association mentions the first fresh air school founded in Providence, R. I., in 1908, and the first preventorium in Farmingdale, N. J., in 1909. Now there are 173 institutions providing preventorium care. New York as early as 1909 authorized the building of county tuberculosis hospitals; now there are almost 200 besides more than

1,000 other federal, state, city and privately owned institutions giving special care to the tuberculous. Michigan was the first state to use the "traveling clinic" to locate isolated cases in rural areas. In 1920 the association formed a committee on medical research, which organized and coordinated the work of individuals and groups. The first "early diagnosis campaign" was conducted in the spring of 1928. Tuberculosis associations are also concerned with the problem of the recovered patient, the first workshop for such patients having been established in New York in 1913.

**Society News.**—Officers of the Southern Sanatorium Association, elected at the recent annual meeting at Hot Springs National Park, Ark., are Drs. John Donnelly, Huntersville, N. C., president, and Paul A. Turner, Louisville, secretary.—Dr. Edward J. Murray, Lexington, Ky., was chosen president of the Southern Tuberculosis Conference at the recent annual meeting at Hot Springs National Park, Ark., and Mr. James P. Kranz, Nashville, Tenn., secretary.—Dr. Alan M. Chesney, Baltimore, was chosen president-elect of the Association of American Medical Colleges at the recent annual meeting, and Dr. Edward S. Ryerson, Toronto, was installed as president. Dr. Loren R. Chandler, San Francisco, is vice president; Dr. Arthur C. Bachmeyer, Chicago, treasurer, and Dr. Fred C. Zapffe, Chicago, secretary. The next annual meeting will be held in San Francisco, Oct. 24-26, 1937.—Dr. Percival S. Rossiter, Washington, D. C., was installed as president of the Association of Military Surgeons of the United States and Canada at the recent annual session in Detroit. Vice presidents are Drs. Arthur E. Lord, Plano, Ill.; Frank R. Keefer, Washington, D. C., and Harold D. Corbusier, Plainfield, N. J. Major Gen. Harry L. Gilchrist, Washington, D. C., was reelected secretary.—At the annual meeting of the Tri-State Medical Society in Longview, Texas, October 26, Dr. John D. Young, Shreveport, La., was elected president, succeeding Dr. Dunbar R. Baber, Daingerfield, Texas, and Joseph M. Gorton, Shreveport, secretary-treasurer. The next annual session will be held in Shreveport.

### Government Services

#### Expansion Program of Veterans' Administration

When the present program of hospital construction is completed by the Veterans' Administration, there will be available 12,914 additional beds. Of these, 8,993 will be for the treatment of neuropsychiatric patients, 1,576 for general medical and surgical patients, 157 for tuberculosis, and 2,188 for domiciliary purposes, as in soldiers' homes. A total of 3,888 new beds will be added during the current fiscal year under the administration's building project, which provides for additional beds in forty-two of the existing hospitals and the erection of five new facilities. Appropriations made available by Congress Feb. 2 and Aug. 12, 1935, and March 19, 1936, totaled \$29,015,420.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Oct. 10, 1936.

#### Report of Committee on Weil's Disease

It is only since the war that Weil's disease (*spirochaetosis icterohaemorrhagica*) has been identified in this country, but of late it has been observed in an increasing number of occupations. The result is that in July 1935 the government appointed a committee, with Sir Humphry Rolleston as chairman, to report whether the disease should be scheduled as an industrial one under the workmen's compensation act. The committee has now presented its report, recommending that this should be done and giving an important survey of our present knowledge of the disease. The committee points out that, while "Weil's disease" (first described by Weil in 1886) is used as a synonym for infection with *Leptospira icterohaemorrhagiae*, it is liable also to be used to cover cases of illness not due to this organism. The use of such terms as *spirochaetosis* or *infective jaundice* might give rise to confusion for the following reasons: 1. Other spirochetes produce forms of disease that might be described as "spirochaetosis." 2. Infection with *Leptospira icterohaemorrhagiae* does not always produce jaundice. 3. Other kinds of infective jaundice, such as epidemic catarrhal jaundice, occur, especially among school children. The nature of the infection was discovered in Japan in 1914 but did not become known in this country until 1916, after outbreaks among troops on the Western Front. Cases have been reported from Germany and Holland. In the latter many have been due to bathing or immersion in canals.

#### INCIDENCE IN GREAT BRITAIN

Though only now about to be made notifiable in England, the disease has been notifiable since 1924 in Scotland. The number of cases notified between the beginning of 1924 and October 1935 was 424, but about half of these related to school-children and were regarded as epidemic catarrhal jaundice. Of the remaining cases some were doubtful, reducing the number of accepted cases to seventy-seven, twenty-three of which were fatal. The occupations were miners (twenty-five cases), fish-workers (thirty-eight), agricultural workers (six) and miscellaneous (eight). In England and Wales a number of cases have come to light, particularly of late, in sewer workers, miners, farm workers, scavengers, butchers and others. There have also been cases apparently due to bathing or accidental immersion in water. For the decade 1925-1934 deaths registered in England and Wales as due to Weil's disease numbered thirty-seven, of which thirty-two were in males and five in females. In a considerable number no occupational source could be suggested. Outside Scotland the disease is not known to have occurred in miners. In many of the cases the diagnosis was based on clinical observations. It is evident that the true incidence of the disease in this country cannot at present be estimated, but the inference is drawn that most of the cases were of occupational origin.

#### SOURCES OF INFECTION

The sewer rat is the main carrier of *Leptospira icterohaemorrhagiae*, but no manifestations of the disease are produced in it. The organism persists in the animal over a long period and is excreted in the urine, from which man is directly or indirectly infected. Moisture appears to be essential for its persistence outside the rat, and man is usually infected by water or slime in places infested by rats, such as mines, sewers, fish-cleaning premises, piggeries and slaughterhouses, or by bathing in polluted water. Thirty per cent of London rats were found to be carriers of *Leptospira*. It may enter the

human body through skin abrasions or the mucous membrane of the nose or alimentary canal (from contaminated food). Dogs may be infected and, as they excrete the organism in their urine, may be sources of human infection. The incubation period varies from four to nineteen days.

#### SYMPTOMS

There are fever of sudden onset, frequently with rigors, intense pain and muscular tenderness, congestion of the conjunctiva, jaundice, hemorrhagic herpes on the lips, and hemorrhages into the skin and from the mucous membranes. But some of these may be absent. In Holland, in 1932, 61 per cent of the cases were without jaundice.

#### DIAGNOSIS

There is little to distinguish the disease from acute necrosis of the liver. A mild infection may be mistaken for influenza or rheumatism. The committee therefore says that compensation should not be based solely on clinical evidence. The diagnosis should be based on finding the *leptospira* in the blood or urine or on a serologic test—agglutination or adhesion (adhesion of the motile bacilli, such as *B. coli*, to the *leptospira* in dilutions of the patient's serum). The medical witnesses said that, in view of the practical difficulties of examination of the blood and urine and guinea-pig inoculation, serologic examination will be the most convenient and reliable method.

#### The Mechanization of Medicine

In an inaugural address at the opening of the winter session at Westminster Hospital, Lord Horder dealt with the mechanization of medicine. As examples of efforts to mechanize medicine, he took the exploitation of instruments of precision, the elaboration of bacteriologic and biologic methods, the commercializing of pharmacology, and the rapid sequence of new machinery in physical therapy. There was good in all these things, but if they were not careful they would overlay and replace the most essential factor in the diagnosis and treatment of disease—the personal contact of doctor and patient. The patient would not save himself from this danger. He had seen most of the rest of life mechanized, so why not medicine? His faith in a piece of apparatus was pathetic. He knew what his blood pressure ought to be. The instrument makers were now dictating standards, as though the doctor's patient might not express individuality even in blood pressure. The doctrinaire attitude toward diet adopted by certain pundits seemed to make a great appeal to many patients. They seemed to think that any day now medicine might discover a standard diet, if it had not done so already. It was the doctor's business to counter all this and to reveal the patient to himself. His whole duty was to examine carefully, explain clearly and watch diligently. If he was of necessity a humanist in former generations, it behooved him to be all the more humanist today.

#### National Health Program

Addressing an important political meeting, Mr. Chamberlain, chancellor of the exchequer, said that the government would cooperate with the local authorities to secure for the younger generation greater opportunities to improve their physical condition—a need which was particularly great in view of the progressive decrease of our population in sight. This announcement has evoked widespread approval. In a communication to the *Times*, Sir Kingsley Wood, minister of health, said that the time had come when we must look more and more at our national health and the services that are provided from a new angle. There were four main objects to which our national health policy should be directed. First, we must go steadily on with our existing work and increase it wherever desirable. A healthy nation must largely depend on healthy environment. The great effort to improve the housing conditions must be vigorously maintained. The slum clearance campaign is now

about half way through its course. Already 500,000 slum dwellers have gone to better homes. An equally important campaign against overcrowding has just begun. Secondly, we must fill gaps in our health services. There is, for instance, a gap in the provision made for the time when children leave school and the time when they enter employment and national insurance. Another project is to make available to every mother, whatever her circumstances, a competent midwife. Thirdly, we must develop a more positive policy in the matter of health—a policy that not only safeguards against disease but actively promotes health. We should have a much greater development of the facilities for physical recreation and exercise. Our people are living some fifteen years longer than their forefathers, but we must make sure that those longer years are worth living; and life to be worth living must be healthy and vigorous. We should remember that when young people leave school they need more than ever opportunities for exercise and the maintenance of health. The steady growth of open spaces and modern town planning are two of the best signs of the times. It is a very good thing that some millions were spent last year on recreation grounds and swimming pools. We depend too much on drugs and bottles of medicine and not enough on personal hygiene. Fourthly, we must bring home to the people the valuable public health services available and also the value of self equipment for health. Publicity and propaganda are necessary.

#### Physicians and Air Raid Precautions

Plans for providing antigas instruction for physicians were described by Major Stuart Blackmore, medical adviser to the air raid precautions department of the home office, at a meeting of branch secretaries of the British Medical Association. Of the three forms of bomb used in air attacks—high explosive, incendiary and gas—he placed gas last but only on the proviso that the population was educated and protected and educated in antigas measures. Gas used against an unprepared, uneducated and unprotected population was a quite different matter. The aim of the gas bomb would then be achieved—an effect on the morale of the nation. It was therefore vital that the medical profession should know all about gas, since it was one of the main supports of the national morale. Gas, labeled definitely as a scientific subject, was one of the things a physician would be expected to know about by his patients. As a result of long thought and much deliberation with various representative medical bodies, a scheme had been evolved. Ten physicians had been selected and had attended or were actually attending the Civil Anti-Gas School in Gloucestershire. These ten would be centered in various places throughout the country closely connected with medical schools, because one of their duties would be to train medical students. They would also instruct the practicing physician. For this purpose the machinery of the British Medical Association had been freely offered and gratefully accepted. The air raids precaution department intended to place some forty or fifty trained units in various localities. Each unit would draw classes from an area of from 10 to 15 miles. Then the unit would be shifted to another locality and the procedure repeated. Nothing less than twelve hours' instruction was likely to be sufficient. Major Blackmore suggested six periods of two hours each, one hour of theoretical and one hour of practical instruction. Whether that instruction took place six days in succession or one day a week or a fortnight was a matter of local arrangement. The government would provide the instructors and equipment free of charge. The maximum in a class should be sixty, but from the point of view of practical instruction from thirty to thirty-five was a better number. A series of handbooks on the subject had been published by the government, of which one was clinical and designed for the medical profession. Gas masks would be available during the course. Mobile gas chambers, of which

some thirty-five or forty were already scattered about the country, would be available for instruction. The response to the scheme had been overwhelming and it would be necessary to increase the number of medical instructors.

#### New Altitude Record

The air ministry announces that a new high altitude record has been made by Squadron Leader Swain, who attained a height of 49,967 feet, breaking the previous record, established in August, by 1,269 feet. A sealed pressure suit enabled the pilot to remain very high for nearly two hours while he endeavored to attain the maximum height possible. The minimum pressure observed was 92 mm. of mercury and the lowest temperature —49.8 C. In the *British Medical Journal* Group Captain G. S. Marshall of the staff of the Central Medical Establishment of the Air Force has made the following commentary on the performance: Human beings are adapted to an air pressure of 15 pounds to the square inch but their tolerance is such that they can live, if doing no appreciable physical work, at an atmospheric pressure a little more than half this. At a height of 18,000 feet the atmospheric pressure is one-half that at the ground level and therefore the oxygen pressure is insufficient for full human activity and so has to be supplemented either by increasing the percentage of oxygen in the air inspired or by increasing the pressure within the subject's lungs. The former is the most practicable but, even when carried to the limit of breathing pure oxygen, is inadequate for altitudes much exceeding 43,000 feet. At this height breathing pure oxygen is physiologically comparable to breathing air at 15,000 feet, usually regarded as the safe limit for flight without oxygen. Beyond 43,000 feet some means of artificially increasing the pressure in the lungs, either with or without the use of additional oxygen, is necessary. This cannot be done to any useful extent without balancing the pressure within the lungs with that outside them. The subject's immediate atmosphere has to be maintained at least at a pressure equivalent to that of the atmosphere at 43,000 feet. This can be done by subjecting him to a pressure slightly above that of the atmosphere in an air-tight cabin or air-tight suit. A sort of diving suit of highly specialized character is used, in which a pressure previously determined is maintained.

#### Lord Moynihan's Estate

The gross estate of the late Lord Moynihan is estimated at \$1,615,000. He bequeathed \$10,000 to the Royal College of Surgeons to found an eponymous lecture, to be given at such dates and under such arrangements as the president shall from time to time determine. To the Leeds Medical School, in memory of his mother Ellen Anne Moynihan, he bequeathed \$5,000 to establish an eponymous lecture to be delivered annually, biannually or triannually, as the Faculty of Medicine may decide, by some surgeon not connected with Leeds University, on any subject he may select. After the death of his wife, a week before his own, it was Lord Moynihan's intention to bequeath \$5,000 to Leeds University for founding in her memory an Isabella Wellesley Lady Moynihan scholarship to be given to the winner of the Hey (a well known Leeds surgeon of the late eighteenth century) gold medal, which he had already endowed. He died before he could make the necessary alterations in his will, but the family intend to carry out his wishes.

#### Parallel Evolution

In his presidential address to the British Speleological Society, Sir Arthur Keith brought forward a new theory of the origin of the modern races of mankind. Heretofore anthropologists believed that modern races, black, brown, white and yellow, evolved from a common mid-Pleistocene stock, but recent discoveries in caves were compelling them to recast their ideas. They were now tempted to believe that by the beginning of the Pleistocene period, some 500,000 years ago, the ancestors

of the Mongol, Australian and Negro were already in occupation of the continental areas now inhabited by their descendants, and that after separation each race underwent a similar series of parallel changes, such as reduction of tooth and jaw, enlargement of the brain, and replacement of simian by human markings. In support of this theory, Keith adduced Mongolian, Australian and Negro characteristics observed by him in the skulls of *Sinanthropus* from China, *Pithecanthropus* from Java and Kanam man from East-Africa. It was necessary to reorientate our working theories. Only the independent evolution of the races of mankind during the whole length of the Pleistocene could explain the known facts. This view deepened the mystery of human evolution, for it implied, as in the past, that the future of each race lay in its genetic constitution. Throughout the Pleistocene the separated branches of the human family appeared to have been unfolding a program of latent qualities inherited from a common ancestor at an earlier period.

### Promotion of the Safety of Miners

The report of the Safety in Mines Research Board shows much important work done to promote the safety of miners. For the first time evidence is produced supporting the claim that has been advanced that such increased illumination of the coal face as can be obtained from the electric mains would give greater safety. Progress has been made in the development of protective equipment. During the year, 140,000 hard hats have been supplied to miners. Remarkable figures from a mine working thick seams in South Wales show that in 1933 (when no hats were in use) the injury rate per thousand man shifts worked was 0.79 against 0.075 for 1935, when 85 per cent of those employed underground were equipped with hats. Gloves have been used to an increasing extent, and large numbers of safety boots are in use. The toes and insteps are the parts of the foot most susceptible to injury, but all parts require adequate protection. Eye injuries are among the most serious of nonfatal accidents but can be almost eliminated by wearing properly designed goggles. In certain operations, shin guards, knee pads and elbow pads have proved highly effective in preventing injuries. The knee pads and elbow pads are also of value in preventing "beat knee" and "beat elbow." Safety trousers fitted with removable knee pads are being worn, but some workmen prefer rubber pads sewn into a pocket in the ordinary trousers knees.

### PARIS

(From Our Regular Correspondent)

Oct. 15, 1936.

### Infections Due to *Bacillus Funduliformis*

During the past year several papers on generalized infections due to *Bacillus funduliformis* have appeared. A complete review by Prof. André Lemierre of Paris appeared in the *Lancet*, March 28, and since then two new observations were reported at the May 8 meeting of the Société médicale des hôpitaux by Donzelet, Meyer and Olivier, referred to in a previous letter. At the May 22 session of the same society this type of generalized infection was the subject of three additional communications by Paris internists. The first of these was by Lamy and Fontcaulx on a case of thrombophlebitis of the cavernous sinus with septicopyemia due to *Bacillus funduliformis*. The patient was a girl, aged 4 years, who was admitted to the service of Professor Debré on account of an acute otitis media. Four days later the signs of a bilateral thrombosis of the cavernous sinus appeared. Cultures from the pus of the ear infection and of the blood revealed the presence of *B. funduliformis*. The child died two days later, the final clinical picture being that of a meningitis accompanied by jaundice and pulmonary infection. At necropsy a suppurative thrombophlebitis of both the cavernous and the coronary sinus were found, as well as an extensive osteomye-

litis of the petrous portion of the temporal bone and body of the sphenoid. The authors did not believe that ligation of the internal jugular vein would appear to be indicated in cases of postanginal or postotitic septicemia, because it would not be able to prevent an endocranial thrombophlebitis due to an organism such as *B. funduliformis*, which seems to have a special affinity for the venous circulation.

The second paper was by Lemierre and Moreau on a cured case of septicopyemia following tonsillitis and due to *B. funduliformis*. The patient was a woman, aged 24. The symptoms were so characteristic of *B. funduliformis* infection that this diagnosis was made before it was confirmed by the bacteriologic examination. The onset was sudden in the form of a severe chill on the fourth day of a severe tonsillitis. The following days, and at irregular intervals, there appeared cycles of chills and high fever, signs of pulmonary infarction and arthritis of the spine. This triad alone left little doubt as to the diagnosis, which found its corroboration by a positive blood culture for *B. funduliformis* on the sixth day after appearance of the tonsillitis. In spite of the gravity of the complications, the patient recovered. The authors were of the opinion that this was due to the fact that there were only two minute demonstrable pulmonary foci and no empyema. The chief menace in cases of *B. funduliformis* infection was the existence of multiple pulmonary suppurative foci complicated by an empyema.

The third paper was by Professor Lemierre and three of his associates, Reilly, Heine and Hamburger, and was on ligation of the internal jugular vein in a case of septicopyemia due to *B. funduliformis* and following tonsillitis. The patient was a girl, aged 16 years, with initial symptoms of an acute tonsillitis followed two days later by repeated severe chills and high fever. There was no evidence of pulmonary foci, but the blood culture revealed, on the fifth day after the onset, the presence of *B. funduliformis*. As a prophylactic measure against further dissemination, ligation of the left internal jugular vein was performed but was of no avail, death taking place five days later. Three hemocultures had been positive for *B. funduliformis* during the patient's stay in the hospital. The necropsy revealed the presence of a small amount of pus in both pleural cavities, several foci of pulmonary suppuration, a minute abscess in the deeper portion of the left tonsil and a widespread peritonsillar thrombophlebitis with *B. funduliformis* in the thrombi. The authors stated that if the internal jugular ligation had been performed at an earlier period of the infection the result might have been different. However, this procedure had improved the prognosis of anaerobic infections but little, according to German authors.

### Identity of *Bacillus Funduliformis* and *Fusobacterium Nucleatum*

Among the Parisian internists who have studied generalized infections due to *B. funduliformis* most intensively may be mentioned Prof. André Lemierre, in charge of the large Claude Bernard Hospital for Infectious Diseases, and his associates Grumbach and Reilly. At the June 30 meeting of the Académie de médecine they again called attention to the fact that from the clinical picture alone one is able to recognize a septicopyemia as being due to anaerobic bacteria. These generalized infections appear suddenly after a severe tonsillitis in the form of a triad of symptoms, high fever, pulmonary infarcts (with or without accompanying empyema) and suppurative arthritis. Icterus is less constantly observed but highly significant when present. The lesions occur in such a uniform manner that the specific character of the infection is evident. In the majority of cases the organisms that have been isolated have been anaerobic and gram negative, associated or not with anaerobic streptococci. The difficulty of classifying anaerobic bacteria in general and the frequent occurrence of incomplete

identifications explain why it is impossible to state whether the anaerobes found in these cases belong to one or to several varieties. The authors were able, however, to affirm that the *Fusobacterium nucleatum* isolated in several cases at Zurich is identical with the *Bacillus funduliformis* of Hallé, constantly found at the Claude Bernard Hospital in post-tonsillitis septiciemias since the original report by Teissier, Reilly and Rivalier.

### The Skin Reactions to Tuberculin in Children

A survey has just been made at the clinic of the pediatrician Professor Nobécourt of the tuberculin reactions observed in 1,989 children from 6 to 10 years of age and in 1,776 from 10 to 15 years of age. The detailed statistics appear in an article in the May 6 *Gazette des hôpitaux*. Professor Nobécourt considers the ordinary and intradermal reactions to tuberculin of great value in the detection of tuberculosis in infants and children. One must bear in mind that there are exceptions, such as cases showing positive evidences of the presence of a tuberculous focus with negative reactions and on the other hand one encounters children without any demonstrable focus whose reactions are positive. Every child admitted to the service of Professor Nobécourt in the Hôpital des enfants malades (the largest children's hospital in Paris) is given the ordinary tuberculin skin test on admission and this is repeated at least once a month and finally controlled by the intradermoreaction. The conclusions reached from this study of 3,765 children between the ages of 6 and 15 years, are as follows:

1. The percentage of positive skin reactions is already high during the seventh year. It increases but little between the ages of 7 and 10 years but markedly between the tenth and fifteenth years. During the seventh year it is more marked in girls than in boys. Between the tenth and the fifteenth year it is about the same in intensity in the two sexes. Tuberculous infection appears to occur especially often before the age of 7 years and between the tenth and fifteenth years. Before the age of 7 years it is observed more frequently in girls than in boys, while between 7 and 10 years the reverse is true. From 10 to 15 years the incidence is the same in the two sexes.

2. The percentage of active tuberculous foci is relatively low during the seventh year, being higher in girls than in boys. It increases little from the seventh to the tenth year in boys and to the thirteenth year in girls. Definite increases occur in boys during the eleventh and twelfth years, whereas in girls this is observed during the fourteenth and fifteenth years. During the latter, the percentage is higher in girls than in boys.

3. It is evident that age and sex have a distinct influence on the percentage of positive skin reactions to tuberculin and of active tuberculous foci. This influence is due to endogenous and exogenous factors of complicated character.

### Twenty-Third Annual Hygiene Congress

This year's congress organized by the Society of Public Health and Sanitary Engineering will be held in Paris from the 19th to the 22d of October at the Pasteur Institute. The secretary of public health and Professor Leclainche (president for 1936) will preside. There will be a symposium on the organization of a service of epidemiology (human and veterinary), on associated vaccinations (human and veterinary), on the teaching of hygiene in the veterinary schools and on the services which veterinarians can render in public health efforts. Professor Levaditi of the Pasteur Institute will read a paper on the ultraviruses, and there will be papers on our present knowledge of disinfection and also on the protection of civilians against toxic gases employed in warfare. The Society of Medical Meteorology will hold a special session on October 21 during the congress. Those desiring to attend this congress can obtain all information through Dr. Dujarric de la Rivière at the Pasteur Institute.

### Commercial Exploitation of Pharmaceutical Preparations by Physicians

A bill was introduced during the last session of the chamber of deputies with the object of forbidding any unethical relations between the exploiters of pharmaceutical preparations and any licensed physician. The latter will not be permitted to give free or paid consultations in any establishment where drugs are sold unless the physician owns such a store. The subleasing of a store or office by a physician to any one not practicing medicine for the purpose of exploiting some pharmaceutical preparation is also forbidden. The object of the proposed law, as explained by Dr. Cousin, a Paris deputy, who introduced the bill, is to put a stop to practices now existing in France which are unworthy of the dignity of the medical profession. Many physicians allow their names to be employed as recommending certain drugs because this endorsement greatly aids their sale. It has been proposed to found an "Order of Physicians" in France because it would be easier to discipline those guilty of unethical methods of advertising. Thus far but little progress has been made in this direction although the need of stricter control of those who utilize the radio, weekly journals published by drug houses and similar methods is generally recognized here.

### Professor Gosset Honored

Prof. Antonin Gosset, one of the two heads of the surgical department of the Paris Medical School, was recently elected a fellow of the Academy of Sciences, a much merited honor. In order to celebrate the event, a number of assistants and colleagues of Professor Gosset are subscribing to a fund with which a sword (as is the custom on such occasions in France) will be presented to the new academician.

### The Medical Führer and Unlicensed Practitioners

The national führer of medicine, Dr. Wagner, has recently expressed himself anew on the question of unlicensed practitioners. University professors have generally assumed more favorable attitudes toward the new state, but there are still recalcitrants on whom the National Socialist revolution seems to have made no impression. In discussing the relation of biologic medicine to school (regular) medicine, Wagner stated that the procedures of regular medicine should not be disparaged and that it was not intended to substitute for regular medical knowledge and skill the untried therapeutic methods of biologic medicine. Then too there are the biologic fools, the acquisitive knights-errant of conjecture and the visionaries. Nature cure medicine must be housed within the structure of regular medicine. Every doctor should be a biologic physician and the formal title "biologic physician" should be done away with. The unrestricted practice of medicine (*kurierfreiheit*) and National Socialism can never be made to harmonize. Unlicensed practitioners should not be allowed to treat the sick. (This new official attitude represents a virtual reversal of that which until quite recently was so strongly maintained.) After a certain set date no new candidates will be permitted to become healing practitioners (*heilpraktiker*). This will leave from 4,000 to 5,000 such practitioners, none of whom are licensed physicians, still free to use what methods they please.

The foregoing statements, emanating as they do from the highest official medical sources, become the more interesting when it is considered that the number of lay practitioners in the German reich, according to the almanac of health statistics, has continuously increased in recent decades. The official figures are given in the accompanying table.

Moreover, the Heilpraktiker's League recently undertook a purgation of its membership and expelled all those practitioners who refused to demonstrate their qualifications before an examining board. At present the organization numbers around 5,500 members.

It is further interesting to note in this connection that an exposition in honor of the centenary of the popular healing movement in Germany was held at Nuremberg last June under the patronage of the local district leader of the party, Julius Streicher. Simultaneously, an extremely well attended get-together festival of the Nature Cure organizations was held. The exhibits consisted for the most part of charts and mechanical materials, all serving to illustrate how man is disorientated by civilization and how "the mediator between nature and the human organism is the blood." Manufacturers connected with

alcoholic beverages cannot be dispensed to a person under the age of 16 for his own use excepting in the presence of his parent or guardian.

#### Damage to Liver from Caffeine During Pregnancy

For many years the Berlin anatomist Professor Stieve, formerly of Halle, has studied the action of caffeine on the organism. Recently he discussed before the Berlin Medical Society the results of experiments with hepatic alterations in both pregnant and nonpregnant rabbits. The same breed of rabbits was used throughout. Caffeine was administered in quantities of 0.1 Gm. per kilogram of body weight, in the form of coffee or as an aqueous solution. In some instances the experiment was carried on for a number of years. It was demonstrated that the nonpregnant animals tolerated the caffeine, whereas for the pregnant animals it acted as a decided toxin. Stieve noted that habituation to caffeine is possible within certain limits.

Only a part of the pregnant animals that were subjected to the influence of caffeine brought forth young, and the young of the entire litter would be much smaller than normal. Besides, some or all of the litter frequently died in the first week of life. The lethal factor in these cases is not made clear. It was established, however, that the animals were underweight and in a completely asthenic state; the liver contained much fat, but this was true of all the new-born animals irrespective of the administration of caffeine. The brood rabbits seldom died but without exception presented marked hepatic alterations consisting of central and peripheral fatty infiltration in the lobules. Single cells were increased from ten to twelve times their normal size and the nucleus-protoplasm relation was shifted. Kupffer's stellate cells were completely uninvolved in the degenerative processes. At the end of the gestatory period the liver may resemble a field of debris. Even severe disturbances are still reparable. If the young soon die, regenerative processes set in at once in the bile ducts and in the capillaries. Thus it has been proved by these experiments that the liver of pregnant rabbits possesses a distinct hypersensitivity to caffeine. These experimental observations are interesting, but they should not be considered applicable to man until investigated further.

#### Health Service in the Invalid Insurance

As every one knows, there is in Germany in addition to the sick insurance the equally compulsory invalid insurance, which in addition to benefits for the aged maintains a health service. A financial statement of this service for 1935 has just been published. The gratifying increase in the amount of the contributions received made it possible to expend 50,000,000 reichsmarks for this health service during 1935. Cases of illness involving legitimate claims for treatment by the invalid insurance reached a high figure, in excess of 500,000 in 1930, but for 1933 the corresponding figure stood at 124,000. In 1934 the number increased to 153,000. During the last year there was further increase to more than 200,000. Particularly prominent numerically among these cases are epidemic diseases, tuberculosis, venereal diseases, rheumatism and cancer. In addition to funds disbursed for medical service, substantial sums were in certain instances allocated for the prevention of premature invalidism and for the promotion of sanitary conditions. Among other accomplishments there was the extension of direct treatment in sanatoriums, hospitals and convalescent homes to 18,000 children and youths. The national insurance law further provides that the existing insurance institutions of the various German states may invest a part of their capital in community projects. This policy is in line with two principal aims: amelioration of the housing shortage situation and promotion of the fight against tuberculosis, especially by reducing the possibilities of infection. According to the report, 544,000,000 reichsmarks had been invested in this manner by the end of

#### Lay Practitioners in the German Reich

Year	Number of Lay Practitioners	Number per 10,000 Population	Number per 100 Physicians
1876.....	670	0.16	4.9
1887.....	1,713	0.36	10.8
1909.....	4,468	0.70	14.6
1930.....	12,942	2.01	27.4
1934.....	14,266	2.19	30.2

the nature cure movement and several other groups also exhibited at this exposition. Among the dicta that stared one in the face from the walls of the heilpraktiker's exhibit was this: "If medicine were a science, the sick would be in a bad way."

It is a further significant fact that the Paracelsus Institute of Nuremberg, a center of nature medicine, has at its head that same Dr. von Brehmer who not so long ago attained notoriety by his alleged "discovery" of the causative agent of cancer. This "discovery," as previously reported (*THE JOURNAL*, February 1, p. 394), was rejected both by the official opinion of the national bureau of health and by the foremost workers in the field of cancer research. Another of the signs read: "Not brilliant diagnoses—healing results, the patient demands health," and below it there appeared, as illustrative material, four paradoxical enough photographs depicting the consulting room of a heilpraktiker wherein he is shown testing, one after another, the constitutions of his patients and forthwith diagnosing diseases of the eye and evaluating conditions of the hands and nails. He is also portrayed as determining the condition of all the viscera by auscultation. And the foregoing are only a few samples.

From a perusal of the various sections of the new "penal code" that is about to become law, one gleams that so far as the government is concerned the public health is to be better protected henceforward than by these still surviving fantastic methods of quackery. For example, the section entitled "Offenses Against Public Health" provides, among other things, that any person who violates the ordinance governing the dissemination of infectious disease shall be henceforth liable to a jail sentence or even to a penitentiary sentence. Similar severe penalties apply to a person affected with a venereal disease who shall contract a marriage or who shall indulge in coitus. There is also a strict prohibition of any traffic in food products that may be injurious to health. The latter clause is made to cover the unhygienic packing, storage or transport of foodstuffs and is particularly aimed at the prevention of those cases of food poisoning which result not from human agencies but from natural influences such as decomposition. The penalty for supplying alcoholic beverages to drunken persons in a saloon or retail liquor store has been increased to two years imprisonment. Spirituous liquors or beverages containing a large content of such liquors must not be dispensed to persons under the age of 18 years for their own use. Other

1935. During the same year expenditures for the foregoing purposes amounted to 16,700,000 marks; that is, nearly twice the corresponding figure for 1934. In addition, the insurance organizations have indirectly contributed substantial sums for the construction of dwellings. Around 14,100,000 marks went for the purchase of mortgage debentures, and loans of 13,000,000 marks were granted for the construction of homes for working class families.

### BELGIUM

#### A Dental Program for the Schools

Dr. Watry, who has had experience in the Antwerp schools, recently proposed the following plan for a school dental service: 1. Buccodental disturbances are so prevalent among the school population that only the smallest proportion of pupils remain unaffected by them. Ordinarily the seriousness of these disorders is such that one third of the children are in danger of severe complications with attendant pain and inflammations and hence require immediate treatment. 2. The dental service as it now functions is desperately inadequate in that it tends to minimize the most important two factors in a successful campaign against the scourge of dental caries. The present services attempt, to be sure, to proceed first to a treatment of the lesions presented by child patients. But the incidence of these lesions is so great that, in order fully to discharge its duties, the dental service of any particular school would require for personnel, equipment and expenses generally a sum of money far in excess of that which even the wealthiest and most open-handed administrative body would be disposed to allocate for this purpose. 3. A study from the etiologic point of view of the majority of the buccodental disorders presented by school children leads to a clear enough understanding of the rôle to be assumed by the stomatologist in the dental service as it should be. This concept is based on the following points: (a) Stomatologic inspection in the schools should be founded, above all, on preventive medicine and oral hygiene. The effort must be made to suppress the predisposing and efficient causes of the lesions before the latter have been produced. (b) Special instruction for the child, the parents and the teachers is indispensable. The school physicians should find their most valuable collaborators in the teachers, since the latter group, being versed in pedagogic procedures, are best qualified to indoctrinate the children with the necessary rules of hygiene. It should be further attempted by all possible means to disseminate in the home as well as at school the rudiments of hygiene and to bring the parents to understand the extent of their responsibilities. (c) As the first aspect of the service program is wholly medical in character, it must be entrusted solely to physicians who are specialists in stomatology, and each of these should remain in a close community of ideas and plans with his colleagues of the school general medical service. (d) While the idea of a physician especially trained for school service is admitted, it is out of the question that such a physician should be entrusted with stomatologic examination. Even if a general practitioner exclusively devoted to the school service could acquire an adequate skill in all the specialties, the task imposed on him would, from a stomatologic point of view, be so formidable, so vast, that to grapple successfully with it would be a physical impossibility, were he at the same time to attempt to devote himself with equal energy to other problems, no less important, that would fall to his share. And this holds true even if he were the most energetic, best intentioned doctor in the world. (e) The second or therapeutic phase of the stomatologic service may be introduced according to either of two procedures, each of which possesses its advantages: treatment at the school dental clinic

or at the consulting office of the physician. Whichever method is adopted, the organization of the service must be made to satisfy one important condition: it must place at the disposal of the staff resources commensurate with the needs. Thus each physician will be able comfortably and without danger of being swamped with work, to furnish proper attention to all the children who present dental disturbances, and by "proper attention" is meant such as conforms to all the principles and requirements of modern stomatologic therapeutics.

#### Detection of Color Blindness

Research studies of the detection of color blindness have been carried out by Messrs. De Laet and Van de Calseyde among the personnel of the Belgian navy. Dr. Weekers discussed the results of these investigations before the Royal Medical Academy of Belgium. The speaker declared that these data were of real value, especially to physicians whose duty it was to pass on the fitness of candidates and who accordingly had to be conversant with the best examination methods. The results of these recent investigations parallel in many respects the opinion of the leading ophthalmologic authorities and permit the following conclusions: 1. No one test possesses all the advantages. In selective examinations, therefore, a control by one or several methods, the principles of which differ, should be employed. 2. The pseudo-isochromatic plates of Schaaf, of Stilling and of Ishihara are almost coequal in practical value. Those of Ishihara's test are the better developed and the handier; they permit a quicker and more decisive examination than do the others. The number and the diversity of the plates should be constantly increased in order to avoid any attempt at fraud (which consists in recognizing the plates from memory). 3. The worsted skeins used in Holmgren's test are qualitatively rather insufficient excepting in certain cases of dyschromatopsia. On the whole, the skein test furnishes results identical with those obtained by the various plate tests. Holmgren's test is a meticulously well organized and protracted procedure wherein the examiner's evaluation of the candidate's hesitations may, however, constitute a too subjective element, which may prove a source of error. Hence it would seem advisable to allow other tests to replace the Holmgren. 4. Nagel's anomaloscope provides exact and complete indications; as a rule it clinches the settlement of diagnostic problems and guarantees maximal scientific accuracy. There are extremely rare cases on record, however, in which this instrument has failed to reveal a color blindness which was ultimately detected by one of the other tests. 5. Practical tests of any sort whatever are worthless. They are inequitable in that they fail to submit all the candidates to the same difficult conditions. Such tests are lacking in exactitude, for they cannot combine the diverse circumstances that help to determine the sensorial deficiency of the subject. They are further unsafe in that they afford the candidate too great an opportunity to deceive the examiner by the use of supplementary criteria.

#### Prevention of Biliary Lithiasis

In the Belgian Society of Pediatrics, Dr. Lorand of Karlovy Vary discussed the possible heritability of biliary lithiasis. Stress should be on avoidance of the causes of the disturbance. These are, on the one hand, cholesteremia, stagnation of the bile and its concentration in the gallbladder; and, on the other hand, excessive intestinal putrefaction, with invasion of the bile ducts by bacilli. According to Solomon and Spearry, cholesterol is chiefly eliminated through the intestinal wall. By measures directed toward the intestine, one can accordingly set up powerful aids to the elimination of this excess of cholesterol and in this the dietary regimen plays the most important part. It should consist of vegetables, salads, fruits and black bread—all nutriment rich in cellulose.

To prevent cholesteremia, the ingestion of animal fats must be avoided with the exception of the milk and butter indispensable to the growth of children. Besides milk, the most suitable and most easily digested fat is olive oil cold from the press. Gustave Singer has explained the cholagogue effect of this oil. It is also an excellent laxative.

A regimen composed of milk, legumes, fruits and black bread together with small quantities of meat and fat not only prevents the formation of an excessive amount of cholesterol but works against constipation, that *primum movens* of all disturbances. Purgations are dangerous, as they inhibit the proper functioning of the intestinal nervous system and of Auerbach's plexus. The best laxative is sodium sulfate with a base of Carlsbad water. According to Loeper and Binet, this acts as a good intestinal disinfectant and in addition it facilitates the elimination of cholesterol.

Lorand considers biliary lithiasis an endocrine disease associated with thyroid or ovarian dysfunction.

## BUDAPEST

(From Our Regular Correspondent)

Sept. 26, 1936.

### International Congress of Crippled Children

Delegates to the third World Congress of the International Society of Crippled Children from all parts of the world were greeted by the Hungarian members of the congress in Budapest from June 29 to July 4. The first day being a holiday, the members visited the orthopedic section of the new St. John Hospital and the sanatorium at Svábhegy. Paul H. King of Detroit, president of the International Society for Crippled Children, gave an address, after which the congress went to inspect the National Home for Crippled Children. It was a pity that in consequence of a great downpour which occurred during the afternoon the members could not inspect the workshops, which, being in the basement, were filled with water.

The formal opening of the congress took place on the 30th in the delegation of the parliament. Nicholas Kozma, minister of internal affairs, as representative of Governor Horthy, expounded the government's point of view on the affairs of the crippled and dealt exhaustingly with their social problems. The twenty-five official delegates of the different nations then gave their greeting speeches. I. Kopits of Budapest detailed the orthopedic principles for the prevention of deformity, supporting his statements with statistics. Professor Klima of Brno, Czechoslovakia, accentuated the necessity of controlling methods that are to direct the further fate of the crippled. Miss Copeland of New York presented accurate data to show that in America a considerable percentage of crippling must be ascribed to accidents in childhood.

The second "clinical day" was held in the lecture room of Professor Verebelyi's clinic, where Professor Gocht of Berlin emphasized the importance of the teaching of orthopedics and made known the methods practiced at Berlin University. Professor Spitz of Vienna emphasized the importance of special orthopedic hospitals. Professor Spisic of Zagreb, Yugoslavia, emphasized the rôle of the orthopedic clinics for the treatment of crippled children. Zimmer of Budapest summarized the various modern methods of treatment.

The afternoon was devoted to lectures dealing with the hospitalization of the cripple and to the question of how to protect the cripple after the termination of medical treatment and of how to prevent recurrences. The paper read by P. H. Gnildal of The Hague, describing the care of the crippled in Holland, made a deep impression on the audience. Dr. Szily, the Hungarian state secretary, opened an exhibition showing the treatment and causes of bodily defects. The huge exhibition will remain open until Christmas.

July 2 the meeting was held jointly with the Hungarian Curative Pedagogic Society. L. Lamy of Paris and H. Radl of Vienna discussed the various methods of curative pedagogy. In the afternoon the chief problem discussed was the training of the cripple for an industrial career. P. Koch of Bratislava, Czechoslovakia, discussed the psychology of the crippled. D. G. Buller, delegate from London, read a paper on the difficulties connected with the placement of crippled persons trained in some trade.

Friday, July 3, the laws for the aid of the crippled were discussed. Every delegate read the pertinent law prevailing in his own country. Miss F. Shirley of Chicago and G. Peto of London pointed out the deficiencies of the laws in each country. In the afternoon the committees submitted their proposals and those of B. Horvath, chief secretary of the congress, for the program of the next congress.

### Survey of Budapest Physicians

The number of physicians in Budapest is 2,697, the rate to the population being 1 to 370 persons. There are 291 women doctors. According to age, there are sixty-one who are beyond 70, while most of them are between 30 and 35. There are 1,561 Christians and 1,137 Jews. Thirty-nine per cent of all physicians, men and women, are not married. Four fifths are specialists and only one fifth are general practitioners. Ninety-four per cent of all of them speak German, 33 per cent French, 29 per cent English, 6.6 per cent Italian and 1 per cent Russian. In Hungary a physician who does not live in his own home is not held to be a good doctor. It is thought that since he does not earn enough to buy a house he is not sought for by the people. Only 57 per cent of the physicians have their own household and 40 per cent keep no servants. In Budapest, living is such that everybody must have at least one servant, and in fact even a shoemaker keeps one. Twenty-six per cent of all physicians receive support from their parents, their relatives and even from their children. Thirty-three per cent of all physicians have no telephone, but, what is much more tragic, 17 per cent do not subscribe to even one medical journal. One fifth of all physicians do not possess instruments that they need to carry with them in their medical practice.

## Marriages

BENJAMIN LAKE NOYES to Estelle Reid Hutchinson, both of Stonington, Maine, in Bangor, October 2.

OSCAR WILLIAM CRANZ, Kinston, N. C., to Miss Mary Margaret Hudson of Mooresville, August 7.

WILLIAM HOGE WOOD JR., Philadelphia, to Miss Anne Cary Moss of Parkersburg, W. Va., September 12.

MALCOLM T. FOSTER, Fayetteville, N. C., to Miss Helen Coggins of Spartanburg, S. C., August 11.

JAMES ALLEN KENNEDY, Boston, to Miss Audrey Eleanor Bradford of Nashville, Tenn., in August.

EUGENE M. KELLEY, Exeter, Pa., to Miss Helen Patricia Carr of Waterbury, Conn., August 5.

JOHN NEWTON BOWDEN, Mobile, Ala., to Miss Emily Lasgine of New Orleans, August 19.

JOHN WYATT DAVIS JR., Lynchburg, Va., to Miss Clementene Goode of Utica, Ky., August 20.

WILLIAM EZRA DE VOL, Cleveland, to Miss Frances Hodgins of Brighton, Mich., August 15.

MILTON H. ERICKSON, Eloise, Mich., to Miss Elizabeth E. Moore of Detroit, June 18.

FRANK A. PRATHER, Runge, Texas, to Miss Effie Rowland of Karnes City, August 8.

ARTHUR L. ENNIS, Maroa, Ill., to Miss Bonnie Regan of Decatur, August 21.

CARL BERNARD LECHNER, Erie, Pa., to Miss Dolores Tellers at Emleto, July 22.

## Deaths

**Oskar Klotz**, professor of pathology and bacteriology at the University of Toronto Faculty of Medicine, died, November 3, of myelogenous leukemia, at his home in Toronto, aged 58. Dr. Klotz was born in Preston, Ont., Jan. 21, 1878. He received his M.B. degree from the University of Toronto Faculty of Medicine in 1902 and the M.D., C.M. degree at the McGill University Faculty of Medicine, Montreal, in 1906. He took graduate work at McGill University, the Rockefeller Institute in New York, and in Germany at the University of Bonn in 1905, the University of Freiburg in 1908 and the University of Marburg in 1914. From 1905 to 1907 he was demonstrator in pathology and bacteriology and from 1907 to 1909 lecturer in pathology at McGill University. From 1905 to 1909 he was assistant pathologist to the Royal Victoria Hospital and pathologist to the Maternity and Alexandra hospitals in Montreal. In 1909 he went to the University of Pittsburgh as professor of pathology and bacteriology, which position he held until the end of 1920, and during this period he was director of the laboratories of the Mercy Hospital, director of the Magee pathology laboratory, and from 1916 to 1919 consulting pathologist to the United States Bureau of Mines. He was professor of pathology at the Faculdade de Medicina, São Paulo, Brazil, from 1921 to 1923, having been appointed by the International Health Board of the Rockefeller Foundation. In 1923 he was appointed professor of pathology and bacteriology at the University of Toronto. He also became director of the pathology laboratories of the Toronto General Hospital and consulting pathologist to the Hospital for Sick Children. Among the positions held by Dr. Klotz on various commissions, councils and societies were: member of the National Research Council of Canada; member of the Yellow Fever Commission of the International Health Board in 1926 and 1928; joint chairman of the committee for Canada of the International Society for Geographic Pathology in 1929. He was a member of the Academy of Medicine of Toronto, president 1935-1936; American Association of the History of Medicine; American Association of Pathologists and Bacteriologists, president in 1919; American Society of Tropical Medicine; Association of Medical Museums, president in 1919; Canadian Medical Association; Ontario College of Physicians and Surgeons; Royal Canadian Institute; Society for Experimental Pathology, president in 1935; and fellow of the American College of Physicians.

**Matthew Augustus De Laney** ♂ Brigadier General, U. S. Army, retired, Washington, D. C., died, November 1, at the Walter Reed General Hospital, aged 62, of pyelonephritis and uremia. General De Laney was born in Waymart, Wayne County, Pa., March 6, 1874. He graduated from the Pennsylvania Normal Institute in 1896 and in 1898 received his medical degree from the University of Pennsylvania Department of Medicine in Philadelphia. In 1902 he graduated from the Army Medical School in Washington. He was commissioned a first lieutenant in the medical corps of the U. S. Army in 1901 and passed through the various grades to that of brigadier general in 1932. He served in the Philippines and in Hawaii, and in 1916 he was with the American forces on the Mexican border. During the World War he was in charge of base hospital number 10 and later was detailed as liaison officer with the British War Office. He was assistant executive in the surgeon general's office from 1919 to 1921. From 1928 to 1931 he served as medical adviser in public health and sanitation to Governor Generals of the Philippines Henry L. Stimson and Dwight F. Davis. In 1931 he became assistant surgeon general. In 1933 he was appointed commandant of the United States Medical Field Service School at Carlisle, Pa., where he served until retired in 1936. General De Laney was a fellow of the American College of Surgeons, the American College of Physicians and the American Public Health Association. From 1909 to 1913, during President Taft's administration, he was White House physician. In 1935 he received an honorary degree of doctor of science from the Dickinson College. General De Laney was awarded the Distinguished Service Medal by the United States and the Order of St. Michael and St. George of England.

**Williams McKim Marriott** ♂ San Francisco, dean and professor of research medicine at the University of California Medical School, died, November 11, of pulmonary embolism following appendiceal abscess, aged 51. Dr. Marriott was born in Baltimore, March 5, 1885. He received a B.S. degree from the University of North Carolina in 1904 and an M.D. degree from Cornell University Medical College, New York, in 1910. He began his teaching career as assistant in chemistry at the

University of North Carolina. Subsequently, until he became professor of pediatrics and later dean at Washington University School of Medicine, he taught at Cornell, Washington University and Johns Hopkins. He was a member of the Council on Pharmacy and Chemistry of the American Medical Association from Sept. 23, 1926, to Jan. 1, 1931, and of the Committee on Foods from May 1, 1929, to Jan. 1, 1931. Dr. Marriott was a member of the American Pediatric Society, the American Academy of Pediatrics, the Association of American Physicians, the American Society for Clinical Investigation, the American Society of Biological Chemists, the American Association for the Advancement of Science, and the Society for Experimental Biology and Medicine and an honorary member of the Harvey Society, and a fellow and formerly vice president and regent of the American College of Physicians. He was on the editorial board of the *American Journal of Diseases of Children* and was the author of "Recent Advances in Chemistry in Relation to Medical Practice" and "Infant Nutrition."

**Gilbert Fitz-Patrick** ♂ Chicago, chairman of the professional committee for medicine, Illinois Department of Registration and Education, died suddenly November 12, aged 63, of coronary thrombosis and chronic myocarditis. Dr. Fitz-Patrick was born in Salem, Ohio, Jan. 19, 1873. He attended the Ohio Northern University in Ada and received his M.D. degrees from the Chicago Homopathic Medical College in 1896 and the Harvey Medical College, Chicago, in 1899. He was formerly head of the department of obstetrics at the Hahnemann Medical College and Hospital, Chicago. During the World War he was chief of surgery in a base hospital at Camp Gordon, Atlanta, Ga., colonel in the medical reserve corps of the U. S. Army. In 1927 he was a delegate of the Association of Military Surgeons to the Royal Institute of Public Health in Belgium and the following year was a delegate to the first International Congress of Public Health and Hygiene at Cairo, Egypt. He was past president of the Illinois section of the American Society for the Control of Cancer and of the North Side branch of the Chicago Medical Society, and a fellow and governor of the American College of Surgeons. Dr. Fitz-Patrick was attending obstetrician to the Cook County Hospital and the Henrotin Hospital, consulting obstetrician and trustee of the Illinois Masonic Hospital, and member of the visiting staff of the Passavant Hospital.

**Frank Dearborn Bullard**, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1888; member of the Associated Anesthetists of the United States and Canada; past president of the Southern California Medical Association, the Los Angeles County Medical Association and the Southern California Anesthetists Society; formerly secretary of the Los Angeles Clinical and Pathological Society; at one time instructor of ophthalmology at his alma mater; aged 75; died, September 8, of cerebral hemorrhage.

**Theodore Wellington Corwin**, Newark, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1879; member of the Medical Society of New Jersey; at one time commissioner of public health of the city of Newark; fellow of the American College of Surgeons; aged 79; consulting laryngologist to the Essex County Hospital, Cedar Grove, St. Michael's Hospital and the Hospital of St. Barnabas, where he died, September 1, of cerebral embolism.

**Otis Hardy Maclay** ♂ Chicago; Northwestern University Medical School, Chicago, 1901; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; past president of the Chicago Laryngological, Rhinological and Otolological Society; assistant professor of otolaryngology at his alma mater; on the staff of the Wesley Memorial Hospital; aged 63; died, September 5, of coronary thrombosis.

**William Henry Fisher** ♂ Toledo, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; fellow of the American College of Surgeons; on the staff of St. Vincent's Hospital; president of the Academy of Medicine of Toledo, 1900-1901; formerly professor of clinical surgery at Toledo Medical College; aged 66; died suddenly, September 6, of coronary thrombosis.

**Effa V. Davis** ♂ Chicago; Woman's Medical College, Chicago, 1891; formerly assistant clinical professor of obstetrics at her alma mater and Rush Medical College; owner of the Chicago Maternity Hospital; on the staffs of the Women and Children's Hospital and the American Hospital; past president of the Chicago Council of Medical Women; aged 73; died, October 28.

Karl Ernest Poetker, Portsmouth, Ohio; University of Cincinnati College of Medicine, 1923; member of the Ohio State Medical Association and the Associated Anesthetists of the United States and Canada; formerly city bacteriologist for the city board of health; on the staff of the Portsmouth General Hospital; aged 38; died suddenly, September 21, of heart disease.

Joseph T. De Grange, New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1888; member of the Louisiana State Medical Society; for many years physician for the city fire department; chairman of the first aid committee of the local chapter of the American Red Cross; aged 71; died, September 1, of coronary thrombosis.

Camille Peter Brown @ New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1912; at one time adjunct professor of gynecology, New Orleans Polyclinic; formerly chief surgeon of the Illinois Central Hospital; aged 51; died, September 6, in a hospital at St. Louis, of brain tumor and carcinoma of lymph glands of the neck.

Clark Burnham, Brooklyn; Hahnemann Medical College of Philadelphia, 1881; member of the Medical Society of the State of New York; formerly on the staffs of the Cumberland Hospital and the Skene Sanitarium; aged 80; died, September 3, in the Mount Vernon (N. Y.) Hospital, of carcinoma of the prostate; died after an operation for prostatic obstruction.

William Karg Gray @ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; formerly assistant professor of otolaryngology at the Loyola University School of Medicine; for many years on the staff of St. Anne's Hospital; aged 58; died, September 11, at his home in Oak Park, Ill.

Milton Abe Given @ East Chicago, Ind.; Northwestern University Medical School, Chicago, 1911; served during the World War; formerly health officer of East Chicago; on the staff of St. Catherine's Hospital; aged 47; died, September 13, in the Michael Reese Hospital, Chicago, of injuries received in an automobile accident.

Robert Myers Donald, Moorhead, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; also a druggist; member of the Mississippi State Medical Association; served during the World War; past president and secretary of the Delta Medical Society; aged 54; died, September 9, in the King's Daughters' Hospital, Greenville.

Henry Franklin De Wolf @ Little Rock, Ark.; University of Kansas School of Medicine, Kansas City, 1925; associate professor of dermatology, University of Arkansas School of Medicine; served during the World War; aged 39; died, September 4, in the Baptist State Hospital, of a self inflicted bullet wound.

Robert Hamilton Woodruff, Hackettstown, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1899; formerly member of the state legislature and local board of health; for many years school physician; aged 61; died, September 1, in the Memorial Hospital, New York, of pneumonia.

James Morehead Whitfield, Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1887; assistant surgeon in the U. S. Navy in 1890; for many years city coroner; in 1904 member of the city board of health and in 1907 city chemist; aged 67; died, September 4, of nephritis.

Samuel McClary III @ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1903; formerly assistant professor of surgery at his alma mater; for many years on the staff of the American Oncologic Hospital; aged 59; died, September 20, in the Presbyterian Hospital.

Arnold Henry Bullwinkel, Brooklyn; Long Island College Hospital, Brooklyn, 1913; member of the Medical Society of the State of New York; aged 47; on the urologic staffs of the Swedish Hospital, Kings County Hospital and the Lutheran Hospital, where he died, September 3, of pneumonia.

James Battelle McMillen @ Somerton, Ohio; Starling Medical College, Columbus, 1901; member of the board of education and county board of health; aged 66; died, September 12, in the Community Hospital, Barnesville, of injuries received in an automobile accident.

Charles Carson Deal, Auburndale, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1911; aged 59; died, September 15, in the Morrell Memorial Hospital, Lakeland, of injuries received when an automobile in which he was riding overturned.

Charles A. Carter, Indianapolis; Medical College of Indiana, Indianapolis, 1897; was associated with the city and state boards of health for many years, serving as vital statis-

tician for the state board of health for fourteen years; aged 72; died, September 5.

John Edmund Bryant, Haverhill, Mass.; Dartmouth Medical School, Hanover, N. H., 1901; member of the Massachusetts Medical Society; past president of the Essex North District Medical Society; aged 60; died, September 18, of angina pectoris.

Albert Henry Smith, Philadelphia; Medico-Chirurgical College of Philadelphia, 1888; formerly a member of the division of epidemiology of the state board of health; also a druggist; aged 83; died, August 26, of chronic parenchymatous nephritis.

Louis J. Sintzel, Northbrook, Ill.; St. Louis College of Physicians and Surgeons, 1899; for many years health officer of the village of Northbrook; attending physician to St. Anne's Home, Techny; aged 71; died, August 5, of carcinoma of the bladder.

Charles Forrest Seaton @ Williamsport, Pa.; Jefferson Medical College of Philadelphia, 1908; for many years school physician; on the staff of the Williamsport Hospital; aged 53; died, September 7, when he jumped from a bridge into a creek.

Louis Raehlin @ Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York, 1916; aged 51; on the staff of the Beth Moses Hospital, where he died, September 7, of injuries received when struck by an automobile.

William Fletcher Stone @ St. Albans, N. Y.; University of the City of New York Medical Department, 1890; formerly instructor in and demonstrator of anatomy at Cornell University Medical College, New York; aged 73; died, August 14.

Homer Erastus Rich @ Vernal, Utah; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; served during the World War; aged 50; died, September 24, of heart disease.

Francis L. Borglum, Prescott, Ariz.; John A. Creighton Medical College, Omaha, 1902; for many years connected with the Veterans Administration Facility, Fort Bayard, N. M.; aged 56; died, September 20, of angina pectoris.

Henry Charles Luck, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1894; served during the World War; aged 66; died, September 10, in the Lakeside Hospital.

William Downing Groff @ Nortonville, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1898; aged 70; died, September 19, in the Williamsport (Pa.) Hospital, of cerebral hemorrhage.

Thomas Rene Hyatt, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1905; member of the Kansas Medical Society; aged 79; was found dead, August 27, of heart disease.

Thaddeus Alonzo Casey, Guntersville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the Medical Association of the State of Alabama; aged 75; died, September 6, in Montevallo.

Charles A. Snow, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1892; aged 83; died, August 1, of arteriosclerosis, arthritis, nephritis and uremia.

Luke Henry Crawshaw, Pocatello, Idaho; St. Louis University School of Medicine, 1909; member of the Idaho State Medical Association; aged 56; died, September 5, in a local hospital, of acute appendicitis.

Anne Young, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1898; formerly a medical missionary; aged 66; died, September 30, in the Presbyterian Hospital, of rheumatic heart disease.

Ivy Clare Bedwell, Olive View, Calif.; University of Nebraska College of Medicine, Omaha, 1923; on the staff of the Olive View Sanatorium; aged 40; died, August 25, of acute myelogenous leukemia.

Ralph Bernard Snyder, Schoolcraft, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; aged 48; died, September 8, in the Bronson Methodist Hospital, Kalamazoo.

Charles Newton Cutler @ Plainfield, N. H.; Harvard University Medical School, Boston, 1898; member of the Massachusetts Medical Society; aged 61; died, September 5, of coronary thrombosis.

Wellington James Conover, Evart, Mich.; Milwaukee Medical College, 1900; served during the World War; village health officer; aged 58; died suddenly, September 15, of coronary thrombosis.

**William Wood Ritchey**, Kansas City, Mo.; University Medical College of Kansas City, 1895; St. Louis College of Physicians and Surgeons, 1896; aged 73; died, September 12, of heart disease.

**Charles R. Huckabay**, Idabel, Okla.; University of Dallas (Texas) Medical Department, 1901; member of the Oklahoma State Medical Association; aged 64; died, August 20, of coronary occlusion.

**Byron Charles Leavitt**, Duxbury, Mass.; Harvard University Medical School, Boston, 1887; member of the Colorado State Medical Society; aged 77; died, August 18, of cerebral hemorrhage.

**Waldo Henry Sanford**, New York; Albany (N. Y.) Medical College, 1896; served during the World War; aged 64; died, September 15, in the Harkness Pavilion, Columbia Medical Center.

**Alejandro Ruiz Soler**, San Juan, P. R.; University of Maryland School of Medicine, Baltimore, 1906; member of the Medical Association of Puerto Rico; aged 55; died, September 23.

**Alvan Lothair Chapman**, Hermanville, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1905; veteran of the Spanish-American War; aged 60; died, September 15.

**Samuel Cleveland Seay**, Birmingham, Ala.; Jefferson Medical College of Philadelphia, 1908; aged 52; died, September 12, in the Norwood Hospital, of cirrhosis of the liver.

**Martin George Sullivan**, Winchendon, Mass.; College of Physicians and Surgeons, Baltimore, 1903; member of the Massachusetts Medical Society; aged 57; died, September 14.

**Alexander Lewis Grant**, Los Angeles; University of Edinburgh (Scotland) Faculty of Medicine, 1912; aged 56; died, August 8, of intestinal obstruction and chronic myocarditis.

**Edward Joseph Farrell**, Berwyn, Ill.; Northwestern University Medical School, Chicago, 1907; health officer of Berwyn; aged 53; died, August 9, in the Berwyn Hospital.

**John Stefansson**, Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1911; aged 57; died, September 29, in the Winnipeg General Hospital, of lobar pneumonia.

**Robert Scott Miles Jr.**, Tacoma, Wash.; Minneapolis College of Physicians and Surgeons, 1903; veteran of the Spanish-American War; aged 60; died, August 10.

**Emery Thompson** Ⓢ Holden, Mo.; American Eclectic Medical College, Cincinnati, 1893; past president of the Johnson County Medical Society; aged 68; died, August 9.

**Martin Wesley Page**, Denver; Western Reserve University Medical Department, Cleveland, 1886; aged 74; died, September 6, in the Mercy Hospital, of cerebral hemorrhage.

**Sulveanus S. Gabriel**, Piqua, Ohio; Baltimore Medical College, 1893; member of the Ohio State Medical Association; aged 76; died, September 8, of coronary disease.

**Lawrence Haddon**, Haddonfield, Va. (licensed in Virginia under the Exemption Clause of 1895); Civil War veteran; for many years postmaster; aged 92; died, August 4.

**William Albert Landgrebe** Ⓢ Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1909; aged 55; died, August 14.

**Jessie Wilhelmine Robertson**, Tewksbury, Mass.; Tufts College Medical School, Boston, 1911; on the staff of the State Infirmary; aged 50; died, August 5, in Boston.

**James Bennett Crane** Ⓢ Kilgore, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1911; aged 54; died, September 12, of heart disease.

**Jesse S. Flora**, Kokomo, Ind.; Eclectic Medical Institute, Cincinnati, 1892; aged 66; died, September 14, of cerebral hemorrhage and cardiovascular renal disease.

**Abram R. Setzer**, Richland, Ky.; Kentucky University Medical Department, Louisville, 1906; aged 76; was killed, September 10, when he was struck by a train.

**Daniel J. Carey**, Chicago; College of Physicians and Surgeons of Chicago, 1895; aged 61; died, September 24, of cholelithiasis, pneumonia and heart disease.

**Owen James Brady**, Cleveland; Cleveland Homeopathic Medical College, 1903; aged 71; died, September 5, in the Lakeside Hospital, of carcinoma of the stomach.

**George Henry Davis**, Le Roy, N. Y.; University of Buffalo School of Medicine, 1901; aged 60; died, September 18, of chronic nephritis and coronary thrombosis.

**Clarence Morgan Petty**, Ida, La.; Memphis (Tenn.) Hospital Medical College, 1906; aged 54; was instantly killed recently when struck by an automobile.

**J. M. Willson Cannon**, Pocatello, Idaho; Hahnemann Medical College of Philadelphia, 1878; aged 85; died, September 6, in a local hospital, of heart disease.

**Bernard Cheston Goldberg**, Baltimore; Southern College of Medicine and Surgery, Atlanta, Ga., 1913; aged 52; died, August 31, of coronary thrombosis.

**Charles Milton Ford**, Kew Gardens, N. Y.; University of the City of New York Medical Department, 1888; aged 73; died, September 4, of heart disease.

**Joel Hudson Smith**, Jenkinjones, W. Va.; Medical College of Virginia, Richmond, 1933; aged 33; died, August 20, in the Bluefield (W. Va.) Sanitarium.

**Elinor Edgar**, New York; Cornell University Medical College, New York, 1933; aged 41; was found dead, September 12, of gas poisoning, self administered.

**John Hunting Cobb**, Binghamton, N. Y.; Albany (N. Y.) Medical College, 1891; aged 71; died, September 7, of diabetes mellitus and chronic nephritis.

**Joseph Thomas Sutton**, Milburn, Ky.; Missouri Medical College, St. Louis, 1863; aged 95; was found dead in bed, August 2, of arteriosclerosis.

**Samuel Cloyd Vaughn**, Patton, Mo.; St. Louis College of Physicians and Surgeons, 1902; aged 64; died, August 15, in a hospital at Cape Girardeau.

**Adam William Feltmann**, Chicago; Jenner Medical College, Chicago, 1896; aged 72; died, September 3, of myocarditis and chronic nephritis.

**John Graham**, Pembroke, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1886; died, August 7, in the Ontario Hospital.

**Jefferson Warren Hawthorne**, Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1896; aged 63; died, August 29.

**Clarence S. Robinson**, Dowagiac, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1889; aged 77; died, September 5.

**George Frederick Maddock**, Flushing, N. Y.; University of the City of New York Medical Department, 1889; aged 73; died in September.

**Oliver Angus McCall**, East Aurora, N. Y.; University of Buffalo School of Medicine, 1912; aged 56; died, August 7, of rectal abscess.

**Anna G. Sedam-Benner**, Cincinnati; Presbyterian Hospital and Woman's Medical College, Cincinnati, 1895; aged 72; died, August 15.

**Howard Malcolm Byall** Ⓢ Montpelier, Ohio; Rush Medical College, Chicago, 1884; aged 77; died, September 5, of angina pectoris.

**Isidor Davidson**, New York; Columbia University College of Physicians and Surgeons, New York, 1904; aged 55; died, September 18.

**Raymond D. Pearson**, Monroe, N. C.; Medical College of the State of South Carolina, Charleston, 1922; aged 39; died, September 14.

**John B. Bates**, Verdigr, Neb.; College of Physicians and Surgeons, Keokuk, Iowa, 1890; aged 76; died suddenly, August 22.

**Silas Nathaniel Jackson**, Leavenworth, Kan.; Meharry Medical College, Nashville, Tenn., 1894; aged 66; died, August 4.

**James W. Greenwood**, Fort Worth, Texas; Dallas Medical College, 1903; aged 63; died, August 11, in a hospital at Dallas.

**Hill Everett Pearce** Ⓢ Tarrant, Ala.; Birmingham Medical College, 1908; aged 58; died, September 1, of heart disease.

**Arthur Dalton Smith**, Mitchell, Ont., Canada; Trinity Medical College, Toronto, 1882; aged 77; died, August 30.

**Frank Walter Burns**, Pomona, Calif.; College of Physicians and Surgeons of Chicago, 1896; aged 65; died, August 28.

**Lee C. Carder**, Hull, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; aged 83; died, September 5.

**Edgar L. Walker**, Gladewater, Texas; Eclectic Medical Institute, Cincinnati, 1889; aged 67; died, August 28.

**Mark Dunning**, Orangeville, Ont., Canada; University of Toronto Faculty of Medicine, 1891; died, August 22.

### HEMOLYTIC JAUNDICE—SPHEROCYTIC ICTERUS

*To the Editor:*—It is well known that many conditions can produce jaundice through an excessive destruction of erythrocytes; i. e., a "hemolytic jaundice" in the general sense. Also a clear cut hereditary disease, "chronic hemolytic jaundice with splenomegaly," has been recognized for many years, whether in the congenital form of Chauffard-Minkowski or the so-called acquired type of Hayem-Widal. This disease has unusually concise diagnostic criteria, especially the increased fragility of the erythrocytes in hypotonic salt solution, and small erythrocytes (microcytes), which tend to a more spherical form than normal. As Russell Haden has pointed out, this inherited change in form underlies the increased fragility. The disease has long been known under several, often cumbersome, names, and this is perhaps the reason it is often colloquially spoken of by the confusing, more general, term "hemolytic jaundice." Allen Whipple, for instance, has found it necessary in his Combined Spleen Clinic to separate it from less specific forms by the term "typical hemolytic jaundice." It therefore seems desirable to substitute a more illuminating term, as short as possible, and I suggest "spherocytic jaundice," which also has the advantage of an etiologic implication; "jaundice" rather than "anemia" because, as Chauffard pointed out, these patients may not be anemic and may even be more jaundiced than sick. "Spheroidocytic" would be the more accurate, as the cells are far from true spheres; however, recommendation of the shorter term can take advantage of one of the dictionary definitions of the sphere as "a rounded body approximately a sphere." Therefore, as "spherocytic jaundice" is a less unwieldy term, and as the word "spherocyte" already appears in at least one medical dictionary, it seems the preferable one to use. I do not know of either of these terms having been previously proposed; they may well have been, however, as they seem rather obvious. If so, I can only apologize to the true originator for an unintentional plagiarism.

E. B. KRUMBHAAR, M.D., Philadelphia.

### CINCINNATI COMMITTEE ON DIABETES

*To the Editor:*—I have just seen an editorial in THE JOURNAL (October 31, p. 1473) about the New York Diabetes Association. In May 1935 we organized the Diabetic Committee of the Public Health Federation with the approval of the Academy of Medicine of Cincinnati.

We picked a few men from all the hospitals and insurance companies consisting of a committee of about twenty and had a few informal meetings and then finally organized and I will give you a copy of our set up. Since our organization we have been very active and have received \$1,100 from two insurance companies to assist us in carrying out our programs.

Last fall we invited Dr. Joslin here and he spoke before the general public in one of the local hotels in the afternoon and before the Academy of Medicine in the evening. The afternoon attendance was phenomenal, as there were over 750 lay people at the meeting. In addition to this we have had a girl telephoning all the doctors in metropolitan Cincinnati to find out the number of diabetic patients in this area and I think we have a pretty good idea; we also have had very extensive newspaper publicity and have run over twenty articles in the newspaper about diabetes. This has all been done under the sponsorship of the Academy of Medicine and the Public Health Federation and there have been no criticisms from the profession. This fall we plan to make a critical analysis of the causes of death for 1935 in Cincinnati of all the patients with diabetes who

have died and we are trying to get up a standard history sheet for all the hospitals so that after a five year period we may be able to analyze our data. We also are cooperating with the Cincinnati Better Business Bureau and think we have excluded many of these fake lectures on diet from the public halls of Cincinnati and are going to be on an active campaign against stores who are selling special foods for the diabetic illegitimately.

At the public meeting and at the scientific meeting in the evening, we had a very large exhibit. This year we plan to have more publicity and undertake another public and scientific session. I hope that this note may be of interest to you.

CECIL STRIKER, M.D., Cincinnati.

Chairman of the Committee on Diabetes  
of the Public Health Federation.

### SALMONELLA SUIPESTIFER NOT THE CAUSE OF HOG CHOLERA

*To the Editor:*—*Salmonella suipestifer* is not the cause of hog cholera nor is hog cholera communicable to man. Belief to the contrary excites unnecessary anxiety in communities afflicted with outbreaks of hog cholera. The situation has been aggravated by a recent article in THE JOURNAL (August 1, p. 331) entitled "*Salmonella Suipestifer* Bacteremia." In the introductory paragraph it was stated that the *Salmonella suipestifer* organism is "known to be the cause of hog cholera," and that there is "increasing evidence of its definite relationship to human disease." That such an etiologic error with respect to hog cholera should represent the individual beliefs of the three co-authors of the article, and, in addition, should pass your editorial scrutiny, indicates a widespread misapprehension concerning this disease.

Hog cholera is caused by a filtrable virus—a discovery made more than thirty years ago by scientists of the federal Bureau of Animal Industry. The virus is highly species specific. Aside from some dubious results with guinea-pigs, it has never been propagated in species outside the family Suidae.

*Salmonella suipestifer* is commonly a secondary invader in hog cholera, so commonly, in fact, that it was earlier supposed to be the causative agent and it was accordingly first named *Bacillus cholerae-suis*. The swine disease produced by it is salmonellosis. Outbreaks of salmonellosis in swine, whether or not associated with hog cholera, have not appeared to induce an unusual incidence of gastro-enteric, pulmonic or septic infections among persons who handle, or dwell in proximity to, the affected animals.

JOHN R. MOHLER, V.M.D., D.Sc., Washington, D. C.  
Chief, Bureau of Animal Industry,  
U. S. Department of Agriculture.

### LONG SERVICE FOR ARTIFICIAL EYE KEPT IN SITU

*To the Editor:*—Some years ago a patient of mine who lost his eye in the Civil War came in to see me with the artificial eye broken in the socket. It had grown fast and I had to dissect it loose in its entirety. The glass was porous and badly corroded. I asked the patient how long since the eye had been taken out. He thought for a short time and answered that the eye had not been out of its socket even at night for more than twenty-five years.

I do not think this is a record but at any rate it is a long time to wear an artificial eye.

WILFRID HAUGHEY, M.D., Battle Creek, Mich.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### PERMANENT WAVE SOLUTION AND DERMATITIS

*To the Editor.*—A white woman, aged 23, has been a beautician for five years. Three months ago an eczematous dermatitis developed on the medial and lateral aspects of the fingers and one adjacent to the thenar eminence over the wrist joint. The lesions are typically papular, weeping, intensely itching and minutely ulcerating. She presents evidence of a high carbohydrate diet, recent contact with horses, symptoms of a constitutional hepatic dysfunction and a constantly alkaline urine. Thus far the entire local preparations have been exhausted with no effect, including x-ray therapy. At the present time I am employing dicalcium phosphate wafers and dilute hydrochloric acid and am recommending rubber gloves while the patient is at work, coupled with a diet of carbohydrate 60, protein 60, fat 120. What is contained in the commercial permanent wave solutions? If the dermatitis is due to this solution, what could have gone wrong constitutionally after five years of employment? What beneficial effects could I expect by removing her from her employment for one month? What are your suggestions in a case of this nature? There is no evidence of tuberculosis, syphilis or scabies. Please do not publish name.

M.D., Wisconsin.

*ANSWER.*—The commercial permanent wave solutions contain, among other things, gum tragacanth, linseed gum, quince seed gum, acacia, Karaya gum (a white or gray powder obtained from the sap of a tree grown chiefly in India), boric acid, sodium, potassium and ammonium carbonates, alcoholic keratin, petrolatum and waxes. These substances usually exist in various combinations, depending on the type of preparations used. The Karaya gum is usually employed in the less expensive solutions, the gum tragacanth in the medium priced groups, and the quince seed in the higher priced solutions, along with the other ingredients.

To determine the relationship of the solution to the dermatitis in question, information as to the qualitative composition of the solution used should be obtained from the manufacturer, and patch and scratch tests done with the solution and its respective constituents to determine the offending substances. It is possible that this solution might produce the dermatitis even after five years of employment. The use of the same solution over this period could produce a sensitivity by its cumulative effect as a result of sensitivity developing from a succession of repeated minimal irritations ultimately producing a manifest sensitization in the form of the dermatitis.

Another factor in the production of the dermatitis may reside in the perfume or scent used in some of these preparations. The composition of these perfumes may vary from time to time in different batches of the same preparation and this may have to be investigated, if the preparation is scented.

The contributory rôle of certain foods in producing a sensitive soil and rendering the skin vulnerable to external irritants must also be considered.

If the permanent wave solution is the sole agent in the production of the dermatitis, one should expect a complete recovery by removal of the patient from her employment for one month.

In a case of this type, the patient should first be tested as suggested. The removal of the individual from all contacts that might produce irritation may require a change of occupation. The use of soothing local therapy should be instituted. X-rays, if used at all, should be employed only in cautious, fractional doses. Dicalcium phosphate and vitamins A and D are also of value. The protection of the parts with rubber gloves, if the patient continues work, is excellent. The rôle of foods as agents in the production of an allergic background should be ruled out by appropriate skin testing or elimination diets.

### PECK TEST IN PURPURA

*To the Editor.*—Kindly send me whatever information you have in regard to the Peck test for diagnosis of purpura haemorrhagica.

E. J. WEXLER, M.D., Chicago.

*ANSWER.*—The Peck test for purpura haemorrhagica consists in the intradermal injection of from 0.1 to 0.2 cc. of titrated snake venom solution. Equal amounts of physiologic solution of sodium chloride are injected intradermally at another comparable site. The test should be read at the end of one hour. The production of a purpuric lesion at the site of injection

within a one hour period and a negative control indicates a positive test. An objection to this test may be raised on the grounds that in active and severe cases of purpura haemorrhagica the saline control may be positive, because, in the presence of increased capillary fragility, distention of the skin by physiologic solution of sodium chloride may produce a purpuric lesion. Peck, however, stresses the importance of the test in prognosis (prognostic venom reaction) since it permits a quantitative and qualitative estimation of capillary fragility over a period of time. He has found that patients having a therapeutically induced or a spontaneous remission show a reversal from a positive test to a negative one. Many cases in which the test has been tried have shown a reversal of positive to negative before other criteria of improvement have become apparent. Peck has found that patients with chronic thrombocytopenic purpura who are positive before splenectomy will show a reversal a few hours after operation if the patient has had a favorable result from the operation.

The snake venom used in the test is available through Lederle Laboratories, New York. It is important that standardized moccasin venom (*Ancistrodon piscivorus*) be used. Each 0.1 cc. represents one hemorrhagin unit and different venoms may vary from this standard. The hemorrhagin unit is determined by the amount of moccasin venom necessary to produce hemorrhages in the vascular network of a 3 day old chick embryo.

The test is new and will require more study under varying conditions before its ultimate value can be definitely decided. Peck and his colleagues are doing this and their results will soon be available in medical literature.

### TREATMENT OF SYPHILIS

*To the Editor.*—A man, aged 35, was originally treated for syphilis at the Marine Hospital, San Francisco, in January 1932. At that time he had a genital lesion from which a positive darkfield examination for spirochetes was obtained. The blood Wassermann reaction was repeatedly negative. From Jan. 1, 1932, to May 23, 1934, he received thirty-six injections of arsenicals and thirty-eight injections of a bismuth compound. He was advised to discontinue treatment but to have a Wassermann test made every six months for five years. Jan. 12, 1935, he reported another genital lesion, and again spirochetes were found on darkfield examination. There was no history of exposure outside the family. A diagnosis of primary syphilis was made. There is a possibility that this lesion was merely a recurrence, but the adequate treatment received, the repeatedly negative Wassermann reactions and the negative Wassermann reaction at this time point strongly to reinfection. From Jan. 25 to Nov. 22, 1935, he received a total of 4 Gm. of neoarsphenamine in twelve injections and 4 Gm. of a bismuth compound in twenty injections. During this course of treatment the blood Wassermann reaction was repeatedly negative. However, in July 1935 a spinal puncture was done and was entirely negative except for a gold curve suggestive of cerebrospinal syphilis, 0000111000. Reexamination of the spinal fluid April 9, 1936, gave a gold curve of 2223343000, cell count 0, globulin normal, Wassermann reaction negative. Will you kindly outline the future treatment for this case? There are no cardiovascular or neurologic symptoms at present. If printed in *THE JOURNAL*, kindly omit name.

M.D., California.

*ANSWER.*—As the inquirer remarks, the second lesion of Jan. 12, 1935, sounds much like reinfection. The statement that there was no exposure outside the family implies that the patient is married. In this connection his wife should be examined immediately for syphilis, if this examination has not already been made.

His treatment since the reinfection (or relapse) has consisted of thirty-two injections given over a period of forty-three weeks; i. e., it has not been absolutely continuous. The dosage of neoarsphenamine employed (an average of 0.33 Gm. per dose) is inadequate for the treatment of early syphilis.

The gold curve obtained at the spinal fluid examination in July 1935 is entirely negative and of no significance; the curve obtained in April 1936 is abnormal but, in the absence of other abnormalities in the spinal fluid, an isolated change in the colloidal curve cannot be interpreted without further observation. The colloidal gold reaction is much more variable and more subject to laboratory error than the colloidal mastic or benzoin reaction.

The future treatment of this case should proceed exactly as if the patient had uncomplicated seronegative primary syphilis, and in accordance with the treatment outline suggested by the Cooperative Clinical Group (Stokes and others, *THE JOURNAL*, April 21, 1934, p. 1267). This treatment outline employs the continuous (no rest periods) use of alternating courses of an arsphenamine and a bismuth compound. If neoarsphenamine is used, each course should include from eight to ten weekly injections in a dose of from 0.6 to 0.9 Gm. These courses of neoarsphenamine should be separated by somewhat

shorter courses of a bismuth compound than have heretofore been used; e. g., ten weekly injections of bismuth salicylate 0.2 Gm. each. This scheme of treatment should be kept up for the next six months, at the end of which time the spinal fluid should be reexamined, preferably in more than one laboratory, and two or more different colloidal curves should be utilized. If the spinal fluid is actually abnormal at the next examination, the treatment outline must be changed in accordance with the condition found at that time. If, however, it is normal, as is probable, the outline of treatment suggested should be continued for an arbitrary minimum of one year from this point.

URINARY HISTIDINE TEST FOR PREGNANCY

To the Editor:—I am one of the many young practitioners who have sought outlying towns without hospital facilities and who subsist on small fees largely derived from underprivileged patients. I read your editorial (*THE JOURNAL*, June 27, 1936, p. 2340) on urinary histidine in the diagnosis of pregnancy. I purchased an ounce ampule of Merck's Reagent Bromine, and I wish to use the test, for whatever it may be worth. Would you kindly send me a protocol for this test, especially covering a simple qualitative method? Any information concerning a method of preserving bromine over a period of years would be valuable. I am keeping mine in a glass-stoppered bottle in the refrigerator to begin with.

G. J. POTTER, M.D., Clewiston, Fla.

ANSWER.—Voge in 1929 reported a very simple test for histidine in the urine of pregnant women. He treated 2.5 cc. of urine with 1 cc. of bromine water. A saturated aqueous solution of bromine (bromine water) contains about 3 parts of bromine in 100 of water. This solution is diluted with twice its volume of water for the test. The mixture of 2.5 cc. of urine with 1 cc. of the diluted bromine water is brought to the boiling point. A positive reaction is indicated by a pink or orange red coloration which rapidly fades. In a negative reaction the original yellow remains. Voge found a positive reaction in twenty-four of twenty-five urine specimens that gave a positive Aschheim-Zondek test. In two cases the Aschheim-Zondek test was negative and the histidine test positive, and in thirty-three other cases both tests were negative. Voge found that normal urine does not give this test, the addition of histidine causing a positive reaction. One objection to this simple test is the often rapid disappearance of the red, so that it is difficult to decide the result. Dark colored urines may make the reading difficult.

Kapeller-Adler in 1933 described a specific colorimetric test for histidine too complicated for the average physician's office. To 2 cc. of urine a 1 per cent bromine solution in 33 per cent acetic acid is added drop by drop until a weak yellow persists. After ten minutes 2 cc. of an ammonia-ammonium carbonate mixture (2 parts of concentrated ammonia plus 1 part of 10 per cent ammonium carbonate solution) is added. This is heated in a water bath for five minutes. A deep blue-violet appears, which increases on cooling. After ten minutes a colorimetric determination can be made, a 1:1,000 standard histidine solution being used. Care must be exercised in adding the bromine solution to avoid an excess. For this purpose a potassium iodide starch solution is used.

Földes in 1935 described a modified Kapeller-Adler test, as follows:

To 5 cc. of urine is added in portions of 0.1 cc. a 2.5 per cent bromine solution in 20 per cent acetic acid. The urine is shaken after each addition of 0.1 cc. of bromine solution. When an orange yellow to orange red appears the bromine solution is added until the color reaches its maximum intensity. The reaction may be recorded as from 1+ to 3+. If no color appears, the test is negative. With this test the histidine reaction increases with rise in the specific gravity of the urine.

Kapeller-Adler and Schiller found that the quantity of histidine in the urine varies in the same and in different gravid women. It is greater in amount in the second half of pregnancy than in the first. It is increased by a high protein diet. The histidine was found to disappear on the third day post partum. In nonpregnant women and in males, histidine given by mouth is decomposed and does not appear in the urine. The histidine in the urine of pregnant women is partly endogenous and partly exogenous.

The best manner in which to preserve bromine is in a glass-stoppered bottle under a layer of water. The bromine is heavy and remains below the water, which prevents its volatilization. It can be removed as needed by placing the end of a pipet below the water.

WHISPER TEST OF HEARING

To the Editor:—Would you please tell me if there is any argument as to the method of testing hearing both as to distance 15, 20 and 25 inches and whisper, forced whisper or spoken voice? The audiometer is, I know, the most accurate. I have occasion to do considerable work in this line and find some difficulty in the variance of tests used. Might I also have a list of the various tests of hearing and references?

M.D., Ontario.

ANSWER.—Even though the human voice cannot be standardized with reference to intensity or quality, when used with certain precautions the test is eminently satisfactory from a practical standpoint. The ability to hear the human voice is, after all, the most essential criterion of the hearing ability. The longer the room used for testing, the better. The patient should stand at one end of the room without touching anything but the floor, not leaning against the wall or heavy furniture. The ear opposite the one being tested should be tightly closed with a moistened finger, and the eyes closed or averted from the examiner. The latter should use unaccentuated whisper or whisper conversation, not forced whisper or forced voice. Best for the purpose is the residual air after an inspiration and expiration. The examiner should approach the patient from the greatest possible distance and note at which point the noise or words are first heard. In the English language the numerals are low pitched, except the sixes and sevens, which are high. It is better to see at which distance the patient first hears low tones and then high tones separately, before combining them, as this often gives a clue to the location of the hearing defect, if any. If unaccentuated whisper is not heard until the examiner is within a few inches of the patient, the unaccentuated conversation may be used and the distance noted at which the voice is heard.

Unless an audiometer is of the phonographic type, it is impossible to test speech with it. The most important hearing tests aside from those made with the voice are the Weber to determine lateralization of sound, the Schwabach for noting the duration of bone conduction, and the Rinne for finding the relation of air to bone conduction in the same individual. Other but less important tests are the Bing, the Politzer, and the Stenger test for simulation of unilateral deafness. Following is a list of some of the references from the literature on the functional testing of hearing:

EOSINOPHILIC LEUKEMIA

To the Editor:—Will you kindly let me know the diagnostic criteria of eosinophilic leukemia? How many cases have been reported in the literature? Do you agree with the statement in Price's Textbook of the Practice of Medicine (Oxford Press, 1933) that eosinophilic leukemia is consistent with a very few immature eosinophils in the peripheral circulation? Which of the two is the more dependable sign of immaturity of eosinophils: lobation or the staining of the granules? Is it possible to make a diagnosis of eosinophilic leukemia without examination of a lymph gland section and bone marrow puncture material? Do you agree that as regards the peripheral blood the same criteria should apply as for the other granulocytic leukemia? Please omit name and address.

M.D., India.

ANSWER.—The salient diagnostic criteria of eosinophilic leukemia as summarized from the literature are persistently increased white cell counts as high as 236,000, an unusually large percentage of eosinophils, absence of an etiologic factor to account for the blood picture, a high basal metabolic rate, splenomegaly with but few exceptions, and biopsy evidence of infiltration of the blood-forming tissue with a predominance of eosinophils. The eosinophils in the peripheral blood and the tissues are mostly of the adult type.

There have been about fourteen cases which are grouped in the medical literature as eosinophilic leukemia or persistent hyperleukocytosis with eosinophilia of unknown etiology that satisfy these diagnostic criteria. In ten of the cases reported the disease was chronic in its course, while in four instances the course was acute. Many authorities doubt the existence of a true eosinophilic leukemia because of the predominance of mature forms of eosinophils in the peripheral blood and blood-forming tissue. D. J. Stephen's report, however (*Am. J. M. Sc.* 189:387 [March] 1935) seems quite convincing. In the case that he studied, bone marrow, spleen, lymph nodes and liver showed definite leukemic changes and a significantly higher proportion of eosinophilic myelocytes to mature eosino-

phils than in other tissues. Myeloblasts were present in the peripheral blood and blood-forming tissue. The clinical and pathologic observations were those of acute leukemia. The author employed the term acute eosinophilic leukemia in view of the predominance of eosinophils in the blood and tissue and to differentiate it from other types of myelogenous leukemia. The lack of neutrophilic myelopoiesis was reflected in the scarcity of neutrophilic myelocytes in the bone marrow, the striking lack of neutrophilic granulocytes in the peripheral blood and in necrotizing inflammatory exudates. The chronic variety is reviewed by M. H. Bass (*Am. J. Dis. Child.* 41: 1394 [June] 1931). Some of the cases are not clear and their leukemic nature may be debated.

The statement made in Price's book coincides with the data recorded in medical literature.

The more dependable sign of immaturity is the nuclear structure.

It is not likely that a diagnosis of eosinophilic leukemia could be satisfactorily established without some information regarding the blood-forming tissue.

Too little is known about the eosinophil cell for one to be dogmatic. Apparently from the cases reported if such criteria were used many of them could not be classified as leukemia. This subject needs further study. A correct answer cannot be given to the last question on the basis of abstract reasoning.

#### HAZARDS OF ETCHING INDUSTRY

*To the Editor:*—In a large industrial plant that has been in existence for a number of years, steel frames were copper plated up to six months ago in the following manner: The raw steel frame went through a water washing, sometimes hot and cold combined, followed by a hot potash bath, again dipped, washed in water and finally placed in an electric cyanide bath. No untoward incidents occurred when this method was employed. Six months ago they began what they called an "etching process," which differed only in that the frame was dipped originally in pure nitric and sulfuric acid for about one minute, after which it was washed in a water bath, and the same process gone through as explained. The cyanide solution was held in wooden tubs lined with tar to prevent any form of leakage. The solution itself was made from cyanide eggs and copper cyanide crystals, obtained from reliable companies with whom they have been dealing for many years. Very recently one of the employees who worked at this dipping-etching process developed an ulceration in his nose, was sent to the hospital and subsequently died of pneumonia. Ten other such employees, working at the same process, were afflicted with minor ulcerations, but no further sequelae occurred. The question was raised as to the probable cause for this resulting condition and ammonia fumes were claimed by some to be the possible offender. When I went through the factory, the smell of ammonia fumes was in evidence but not to a marked degree. Do you see any possible reaction in the etching process that would account for the ammonia fumes? If ammonia is liberated, would it cause nasal mucous membrane ulceration? Is there any other chemical liberated that would be injurious? If any injurious substance is liberated, what could be done to prevent such formation? I may add that they have a ventilating system in the plant to draw the fumes out of the building. Also that the foreman in charge, who has been the chief in that department and who has been constantly employed at this etching process, did not suffer any ill effects as the others who were engaged with him in that occupation. Kindly omit name.

M.D., New York.

*ANSWER:*—In the usual course of plating it is unlikely that any ammonia would be utilized or produced. However, a combination of the various pungent odors present might suggest the odor of ammonia. In the situation described, it seems appropriate to attach significance to the mineral acids newly introduced. Whenever mineral acids come in contact with cyanogen compounds, hydrocyanic acid may be produced. Despite rinsing in water after submersion in acid, and despite a bath in alkali solution, it is quite possible for some acid to remain on the acid-etched surfaces of the metal. Notwithstanding the theory that acid baths will not lead to the presence of acid in the atmosphere as the result of evaporation, it may be recognized that through chemical ebullition some acid may be thrust into the atmosphere. This may combine with cyanogen compounds similarly entering the air from nearby cyanide vats. As a result, additional small amounts of hydrocyanic acid may be produced. The ulceration about the nose as described is a fairly characteristic result of cyanide action, although some ulceration of lesser nature might be associated with the action of either the mineral acids or the alkalis. By way of prevention it is suggested that, if the use of mineral acid cannot be eliminated, the rinsing in water should be more thorough, and if possible the contact with the alkali solution should be extended. Lateral suction for the entrainment of fume from all vats is desirable, together with extensive general ventilation, resulting in frequent air change for the entire workroom. While chief consideration is here paid to cyanogen compounds, other respiratory irritants and ulcerating substances

may be found in the mineral acids, in the alkalis, and to a slight extent in the hydrogen evolved in the electroplating process. The specific questions propounded already have been answered. The ventilating system mentioned is likely to be unsatisfactory unless the vats themselves are equipped with intakes, thus entraining the injurious substances near the point of origin. Naturally, hot solutions may be expected to give off a greater quantity of irritating substances than cold solutions.

#### PAIN IN PARALYSIS AGITANS

*To the Editor:*—A woman, aged about 67 or 68, has had Parkinson's disease for the last three years. At first she started out with tremors in the fingers and hand, which later extended to the toes and feet. She has grown progressively worse and has had the usual treatment for paralysis agitans. At the present time she takes about one-sixtieth grain (0.001 Gm.) of scopolamine and at night about 1½ grains (0.1 Gm.) of pentobarbital sodium. For the last two years she has complained of pain in the fingers and wrists extending up the arms; also in the toes and feet and in the back of the neck. There seems to be a marked contraction of the tendons of the forearm and hand, and she gets relief by having some one in the family pull on her hands and arms. I have had to give her one-fourth grain (0.015 Gm.) of morphine at times when she complains of severe pain, but this gives little if any relief. The patient weighs approximately 90 to 95 pounds (41 to 43 Kg.). Her heart and lungs are normal. Urinalysis gives negative results. All the reflexes are normal. The Wassermann reaction is negative. Digestion seems to be normal. There is no vomiting and bowels are quite regular. I am not so much concerned with her paralysis agitans but I was hoping that you could give me some suggestion as to the cause of this pain and also some treatment to give her relief. Kindly omit name.

M.D., Michigan.

*ANSWER:*—The pain in paralysis agitans, with associated paresthesia and a feeling of stiffness, is due to the muscular rigidity. Although there is no specific treatment, drugs of the belladonna group often give relief. They can be used in some patients in surprisingly large doses, spread throughout the day. A patient may take by mouth with impunity as much as six or eight ¼ grain (0.0006 Gm.) tablets of scopolamine hydrobromide in twenty-four hours—four on arising, two at noon and two early in the evening—provided careful watch is kept for untoward symptoms. Massage, the application of heat and muscle stretching also are helpful. Phenobarbital sodium in 0.015 Gm. doses, three or four times a day, ought to add to the patient's comfort.

#### EFFECTS OF KEROSENE FUMES

*To the Editor:*—Given a case in which a worker spends an hour in a tank in which there are enough kerosene fumes to make him nauseated and feel generally ill but still able to continue locomotion, could there be any permanent damage or disability to his nervous system? Please omit name.

M.D., Ohio.

*ANSWER:*—It is impossible at this time to provide an unequivocal answer to this query. Permanent damage following exposures similar to that mentioned in the query has been claimed. One case grew out of the use of petroleum naphtha (which chemically is closely similar to kerosene) as a paint solvent for coating the interiors of metal pontoons. The painter was acutely damaged to about the same extent as that suggested in this query. For many months afterward this workman alleged complete disability for work and furnished many vague suggestions of neurologic disease, most of which suggested malingering or at least a neurosis. Moreover, in this case some possibility exists that carbon monoxide was pumped into the pontoons along with heated air intended to accelerate paint drying. In Hayhurst's series of cases of naphtha poisoning (*Poisoning by Petroleum Distillates, Indust. Med.* 5:53 [Feb.] 1936) the following statement is found: "Periods of exposure have ranged from five weeks to three or four years before employment disability began." However, in other portions of his discussion reference is made to two weeks' exposure followed by two months' disability. It is Hayhurst's conception that petroleum distillates produce their damage at least in part through a dissolving action on the fat of the central nervous system, the medullary sheaths of peripheral nerves, heart muscle and liver. It is noted that chronic cases invariably give the impression at first of malingering, although at a later time substantial proof may arise indicative of organic damage. The onset symptoms are chiefly subjective and are said to include headache, dizziness, loss of appetite, dyspepsia, itching, insomnia, pains in the back, legs and cardiac region, weakness, and shortness of breath. Later, according to Hayhurst, the chief manifestations are marked loss of weight, anxiety, bizarre neurasthenic and psychasthenic symptomatology, increased pulse rate, moderate secondary anemia, slight leukocytosis, skin irritation, lowered resistance to infection, diarrhea, mental depression, muscular twitching and tremors.

## LOW BLOOD PRESSURE WITH SYNCOPE

To the Editor:—A man, aged 45, suddenly fainted. His systolic blood pressure one hour later was 60, but no diastolic pressure could be heard. The pulse rate was 180 per minute, the temperature was normal and no signs of cardiac decompensation were present. Twenty-four hours later his temperature was 101, pulse 200, and blood pressure 80/40. Electrocardiographic examination revealed a PR interval of 0.16, QRS interval 0.04 to 0.06, lead 1 normal, lead 2 a high T wave, lead 3 a slurring QRS, lead 4 a slurring QRS and a monophasic QRS. Twelve hours later the pulse was 80, blood pressure 88/50, and temperature normal. He states that he has always had low blood pressure. Other manifestations are severe frontal headaches, which usually occur in the morning and disappear in the afternoon, possibly an abscessed tooth, and an enlarged prostate. I feel that the low blood pressure is the cause of the fainting spells. I should appreciate any suggestions as to diagnosis or treatment. Are there any drugs, endocrine products or treatments which are of use in raising the blood pressure? Please send me a bibliography regarding causes and treatment of hypotension. Please omit name.

M.D., California.

ANSWER.—It is assumed that hemorrhage has been ruled out. Hemorrhage may be silent and accompanied by little in the way of other symptoms. Hemorrhage from a duodenal ulcer, varices in the esophagus or other sources may appear with no previous symptoms and no obvious sign of hemorrhage at the time.

Epilepsy may first appear as late as 45 or later. Fainting attacks, so called, may appear in aortic stenosis, a lesion that is not as uncommon as it is reputed to be. A paroxysmal attack of some abnormal cardiac rhythm might have been the cause, but that is improbable. A coronary thrombosis is suggested by the fall in blood pressure, the rapid pulse after the syncope attack, and the elevation in temperature twenty-four hours later.

Persons with an abnormally low blood pressure may have syncope attacks from anemia consequent on any factor that is direct blood elsewhere, as to the splanchnic area. Some mild gastro-intestinal disturbance may be responsible for this. In some persons with lax abdominal walls, such a cerebral anemia may follow a change in position from a sitting to an upright position and may be relieved by wearing an abdominal binder. Fainting attacks occur in the so-called effort syndrome a symptom complex characterized by an overlabile autonomic system. Syncope attacks occur also in those with a hypersensitive carotid sinus reflex.

It is impossible to give advice when so few data are available. As a rule, drugs designed to elevate blood pressure are best omitted. The first essential to treatment is diagnosis.

HYPERTENSION, NEPHRITIS AND HEADACHE  
COMPLICATING PREGNANCY

To the Editor:—A married woman, aged 21, whom I first saw on account of pregnancy, had a blood pressure of 125 systolic, 82 diastolic, at first. It gradually went up to 155/90 the last time she was in my office. When I saw her at the time of delivery it was 205/135. No albumin appeared in the urine at any time, and she had no headaches and no spots before her eyes. The blood pressure after delivery was 178/118 and next day was 140/100. Two days later, during a severe attack of gas, it went up to 205/125 and down again the next day as before. Since the arrival of the baby the patient has had frequent and severe headaches with little relief from acetylsalicylic acid or even from codeine. Albumin is found in the urine, with pus cells 2 plus, epithelial cells and casts. The blood pressure is usually around 150/100. I have failed miserably to better her condition with methenamine, enteric coated ammonium chloride pills or a salt free diet. She has no edema but there is a fullness together with a pasty complexion and she still feels worn out all the time. She has a younger brother who has had albumin in the urine for the last six years. I have made a diagnosis of interstitial nephritis. Could this be correct? What can I try for these headaches? What else can I use for the kidneys? Please omit name.

M.D., Nebraska.

ANSWER.—One is curious to learn whether this patient suffered from an acute nephritis in childhood, especially of the type consequent to scarlet fever. The clinical course is such that one immediately suspects a chronic, latent or "silent" nephritis existing before the pregnancy and being acutely and severely exacerbated by it. The existence of proteinuria in a younger brother tends to confirm this impression of probable infective nephritis in childhood. That hypertension did not arise earlier in the pregnancy is evidence that the functional reserve was not severely impaired.

The postpartum drop in arterial tension followed by a rise on the third or fourth day is typical. The delayed rise is frequently to levels higher than those observed just before delivery. It has been demonstrated (Stieglitz, E. J.: Hypertension in Pregnancy, *Arch. Int. Med.* 39:465 [April] 1927) that this delayed rise in arterial tension occurs simultaneously with the onset of lactation and is associated with a correspond-

ing reduction of the calcium content of the blood. The "attack of gas" may possibly have been coincidental.

These patients usually tend to go down hill despite the most energetic therapy, and any further gestations tremendously accelerate the degenerative changes.

The most urgent and necessary study at present is that of the blood. The statement "a pasty complexion and she still feels worn out all the time" is significant. An anemia, perhaps of severe degree, is to be expected both because of the nephritis and because of recent blood loss at the time of delivery. The correction of this anemia is the most imperative therapeutic problem. It is also in many respects the most difficult problem in the management of chronic nephritis. One must not expect rehabilitation and repair of injured tissues if they do not receive an adequate blood supply with all that this implies: ample oxygen to the tissues, ample foodstuffs and efficient removal of metabolic debris. The injury due to hypertension is caused by impaired capillary circulation because of arteriolar constriction, and such histanoxia is tremendously enhanced by simultaneous anemia. If anemia does exist, every effort should be made to build up the hemoglobin content of the blood: parenteral liver therapy, large doses of iron and, if necessary, transfusion of blood. Ferric cacodylate intravenously, in doses of 0.065 Gm. at five day intervals, has proved effective when the hematopoietic structures have not been too severely injured.

## CARBARSONE IN TRICHOMONAS INFECTION

To the Editor:—Kindly advise me if there is any danger (generally and to the tissues themselves) from the use of carbarson suppositories for the treatment of Trichomonas vaginalis vaginitis. If this medication is used, say for two or three courses (thirty-six suppositories) in one month and, in case of recurrence, a course of twelve suppositories monthly, is there not danger from arsenic poisoning? If published, please omit name.

M.D., Massachusetts.

ANSWER.—The first death following the administration of carbarson was recently reported in THE JOURNAL (March 7, p. 769) by Ervin Epstein. The patient took the drug by mouth and in enemas. In spite of this fatal case, carbarson is a relatively innocuous drug even though it contains 28.85 per cent of arsenic and is closely related chemically to trypanamide and acetarsone. Epstein reviews the literature and discusses the reactions that may follow the use of carbarson. The recommended dose in the treatment of amebiasis is 0.25 Gm. twice a day for ten days. This may be repeated after a rest period. Eli Lilly & Co. markets carbarson in capsules of 0.25 Gm. (3¾ grains); hence if thirty-six of these capsules are used over a period of one month the dosage is within the limits of safety. However, Epstein warns that care must be taken in administering carbarson and constant watch must be maintained for signs of intolerance.

## PULMONARY EDEMA

To the Editor:—About twice a year I am called on to treat a case of acute pulmonary edema of cardiac origin. I should make a rough estimate that my mortality is almost 70 per cent. The patients are usually over 70 years of age, with or without known preceding hypertension. Will you please discuss the treatment, including: (a) Digitalis. (b) Venesection; the patients are cold and clammy, the peripheral veins collapsed. I have not seen any indication for a venesection, but some use it. (c) Morphine and atropine. I have used atropine up to doses of one-fiftieth grain (0.0013 Gm.) or even more. With respect to morphine in elderly people, I have hesitated. After one-eighth grain (0.008 Gm.) of morphine sulfate I have seen the respirations become quieter, but the patient became unconscious and shortly died. However, I have seen patients become unconscious without the morphine. I sometimes use dry cupping. (d) Oxygen; I cannot obtain it soon enough in the emergency. (e) With the possibility that some of these cases may be coronary thrombosis, will you please also discuss this. I am under the impression that hypertonic dextrose solutions absolutely do no harm but that aminophylline is still experimental. If published, please omit name. M.D., Pennsylvania.

ANSWER.—The treatment will depend on the condition of which the pulmonary edema is a symptom.

Some cases will be the result of failure of the left side of the heart, consequent on various pathologic conditions but especially following hypertension. Digitalis will be of value in some of these and can be tried in moderate doses for the purpose of increasing tonus and not primarily to slow the heart rate, as the minute volume may be larger with the more rapid rate. It should be tried tentatively and the efforts watched carefully. It may be of value, it may effect no improvement, or it may be a deterrent. One of the mercurial diuretics may be used safely and may be effective. Venesection should be reserved for those cases in which there is an obvious increase in venous pressure; it may be of great value in such cases. Morphine will add to the patient's comfort. Any of the purine

base diuretics, including antitophylline, may be of value. They are not experimental and have been used clinically for more than forty years.

Some of the cases are probably cases of coronary thrombosis and should be treated as such. Absolute rest is the most essential feature of the treatment. Oxygen is of value and can be given successfully by nasal catheter when other means are not available. Treatment cannot be described in detail here.

Some of the cases may be due to the onset of an abnormal rhythm. They are best treated by rest at first and, in cases of fibrillation, by digitalis in full doses if the rhythm does not spontaneously return to normal.

#### REGURGITATION OF FOOD IN ADULT

*To the Editor:*—A woman, aged 42, unmarried, has been having regurgitation now for nearly five years without a great deal of discomfort. Occasionally part of the meal comes up without any effort or straining. There is no pain anywhere, but now and then a slight discomfort in the epigastrium, apparently without any definite connection with meal time. Apparently there is not much acidity. Physical examination is essentially negative except for a rapid pulse, 90, blood pressure 156 systolic, 80 diastolic, and signs of hypothyroidism. The blood and the urine are essentially normal. The basal metabolic rate is minus 20, for which she has been given thyroid with definite improvement in her general feeling. A gastro-intestinal series showed constant regurgitation into the esophagus. The appendix and stomach are normal but there is some generalized ptosis, and downward progress of barium sulfate is slow. Gallbladder functioning is normal except for a rather slow emptying. There is no evidence of stones or adhesions. The duodenal cap is spastic. The lower end of the stomach and the second portion of the duodenum deviate quite far to the right. No defect is seen in the duodenum or stomach. Besides thyroid, she has had acid sodium phosphate bile salts, but slight relief has been obtained only with a calcium-bismuth-magnesium mixture taken at hourly intervals. During the three months of treatment most of her improvements have been only in symptoms associated with low basal metabolism and her weight has come down from 140½ pounds (63.5 Kg.) to 132 pounds (60 Kg.). As far as the regurgitation is concerned, it stays but slightly under control when she is taking the powder every hour daily. Please make some suggestions as to the treatment. I have considered cholecystectomy but am hesitant. Please omit name.

M.D., California.

*ANSWER.*—The noteworthy symptom in this case is the regurgitation of food. It is necessary to consider the condition on a functional basis, since the results of examination, as given in the question, seem to exclude organic disease such as esophageal stricture, diverticulum or diaphragmatic hernia. The demonstration of an irritable duodenal bulb on roentgen examination suggests the possibility of duodenal ulcer, as does the partial relief by the use of alkali. However, if such a lesion exists, it would not result in food regurgitation or in vomiting without evidence of gastric retention during the roentgen examination. Furthermore, the absence of free acid in the regurgitated material would indicate that the food had not reached the stomach, unless free acid is absent from the gastric contents.

If cardiospasm is the cause of the symptom, it should be relieved by the administration of effective doses of atropine. The etiology of the cardiospasm should be determined if possible. An ulcer in the lower part of the esophagus must be considered.

As a further suggestion, it seems advisable to exclude the possibility of a small diaphragmatic hernia through the esophageal hiatus by careful roentgen examination with this condition in mind.

#### POSTMORTEM EXAMINATION OF BRAIN—NECROPSIES ON PRESIDENTS

*To the Editor:*—Can you tell me in what percentage of autopsies the brain is examined and also the spinal cord? Have autopsies been performed on any of the presidents of the United States and what conditions were found? Please omit name.

M.D., New York.

*ANSWER.*—It would not be possible to give the percentages of necropsies in which the brain and spinal cord are examined. The frequency of such examination varies greatly in different places. Generally speaking, the brain is frequently examined as part of the routine, while the spinal cord usually is examined only under special indications.

There are records in medical literature of necropsies on three presidents of the United States: Lincoln (The Medical and Surgical History of the War of the Rebellion, Washington, Government Printing Office, volume II of part I, being the first surgical volume, second issue, 1875, p. 305). Garfield (complete medical record of President Garfield's case, containing all the official bulletins, from the day of the shooting to the day of his death, together with the official necropsy, made Sept. 20, 1881, and a diagram showing the course taken by

the ball, compiled from the records of the Executive Mansion, Washington, 1881), and McKinley (The Official Report on the Case of President McKinley, THE JOURNAL, Oct. 19, 1901, p. 1029). A good many articles have been written about the cases of President Garfield and President McKinley (see Index Catalogue of the Library of the Surgeon General's Office, U. S. Army, second series, Washington, Government Printing Office).

#### ADMINISTRATION OF ACETYSALICYLIC ACID TO INFANTS

*To the Editor:*—The late W. McKim Marriott in his book on "Infant Nutrition" (appendix) gives acetylsalicylic acid in the dose of 1 grain (0.065 Gm.) every four hours for an infant 1 year old. What would be a good vehicle in which to suspend this drug for an infant from 6 months to 2 years of age? Please give several prescriptions. I have noticed that if the powder is not thoroughly moistened before it reaches the throat it causes an unpleasant coughing spell. Does aspiral contain any acetylsalicylic acid? It is a very clear solution. Is the following mixture compatible?

℞ Ammonium carbonate .....	gr. 24
Camphorated tincture of opium .....	dr. 2
Syrup of acacia .....	oz. 1
Water .....	sufficient to make oz. 3

If this query is printed, please omit name.

M.D., New York.

*ANSWER.*—There is no good liquid vehicle for acetylsalicylic acid because it is hydrolyzed by water with the formation chiefly of a salicylate. The addition of potassium citrate does away with the ferric chloride test for salicylates, even though the latter is present in the mixture. The following prescription will serve the purpose.

℞ Acetylsalicylic acid .....	1.0 Gm.
Sucrose .....	5.0 Gm.

Mix and divide into fifteen powders.

A simple way of administering such a powder to an infant is to have the mother dip a moistened finger in the powder and wipe it on the baby's tongue. This will avoid the coughing spell when the dry powder is put into the mouth so that some of the dust is inhaled.

Elixir of aspiral probably does contain some acetylsalicylic acid but no doubt a much larger proportion of salicylate.

The ammonium carbonate mixture is incompatible for several reasons, chief among which is precipitation of the opium alkaloids by the alkalinity as well as the precipitation of the camphorated tincture of opium on the addition of water.

#### TREATMENT OF SQUINT IN BABY

*To the Editor:*—A girl baby, 22 months old, has suddenly begun having an internal squint of the left eye. Her eyes were perfectly straight when she was born. This has come on without any sickness intervening and while the child is in exceedingly good health. I have been advised that it is possibly due to refractive error and am going to have an ophthalmoscopic examination done. Do you think there is any kind of exercise that might be helpful to this child, or do you think that this will disappear without treatment? At the present time we are trying atropine, one drop twice a day, to paralyze accommodation. Please do not publish my name.

M.D., Washington, D. C.

*ANSWER.*—In a 22 months old baby there are really only two measures that may be used in combating squint. The first is a perfect correction of whatever refractive error may be present, the refraction being performed under atropine. The second is the endeavor to develop the amblyopic eye, provided the squint is of the concomitant type. Any competent ophthalmologist can tell by careful examination whether that condition exists.

In a child of that age it is most improbable that the squint will disappear without help. The continued use of atropine for the paralysis of accommodation as a therapeutic measure has not proved particularly successful.

#### CATARACT IN SYPHILIS

*To the Editor:*—Please advise me whether antisyphilitic treatment will cure cataract when there is cataract in conjunction with the mildest possible form of latent syphilis.

CARLETON DEEDERER, M.D., Miami, Florida.

*ANSWER.*—No. Once a cataract has started, regardless of the cause, no known treatment can influence the presence of the opacity of the lens. Arrested progress has been claimed by many through the use of this, that or the other remedy, but the claims have not been substantiated. As far back as 1893, Hirschberg stated that, once diabetic cataract had started, it would progress regardless of a restoration of normal sugar metabolism, and this aphorism holds true for cataract due to other causes.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, Jan. 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Reciprocity*. Los Angeles, Dec. 16. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, Jan. 5. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Endorsement*. Hartford, Nov. 24. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhlman, 203 District Bldg., Washington.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Pfost, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: *Medical*. Des Moines, Dec. 1-3. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines. *Basic Science*. Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

KANSAS: Topeka, Dec. 8-9. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY: Louisville, Dec. 2-4. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

LOUISIANA: New Orleans, December. Sec., Dr. Roy B. Harrison, 1507 Ithier Bank Bldg., New Orleans.

MARYLAND: *Regular*. Baltimore, Dec. 8. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homoeopathic*. Baltimore, Dec. 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 5-6. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEBRASKA: Lincoln, Nov. 23-24. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Endorsement*. Raleigh, Nov. 30. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OHIO: Columbus, Dec. 2-4. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, Dec. 9. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 9-13. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 19. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada in December. *Practical or clinical examination* will be given in St. Louis in April. Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Des Moines.

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. *All applications for this examination must be filed before Dec. 1, and case reports must be submitted before Jan. 1*. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. *Only applications received by the Secretary on Dec. 1 or before will be acted upon by the Board*. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester.

AMERICAN BOARD OF UROLOGY: Chicago, Dec. 4-6. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

### Delaware July Report

Dr. Joseph S. McDaniel, secretary, Medical Council of Delaware, reports the written examination held in Dover, July 14-16, 1936. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventeen candidates were examined, all of whom passed. Five physicians were licensed by reciprocity and 3 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1934)		78.2
Long Island College of Medicine.....	(1935)		82
Hahnemann Medical College and Hospital of Philadelphia.....	(1934) 88.4, 89, (1935) 86.2, 87.6, 89.2, 92.1		
Jefferson Medical College of Philadelphia.....	(1933)		81.1
(1934) 79.3, 80.5, 82.8, (1935) 79.2, 81.4, 82.5, 84.5			
Temple University School of Medicine.....	(1934)		78.6
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Rush Medical College.....	(1909)		Illinois
Harvard University Medical School.....	(1925)		New York
New York University, University and Bellevue Hospital Medical College.....	(1932)		Penna.
University of Pennsylvania School of Medicine.....	(1920)		Penna.
Meharry Medical College.....	(1932)		Maryland
School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Georgetown University School of Medicine.....	(1935, 3)		N. B. M. Ex.

### Hawaii July Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, reports the written examination held in Honolulu, July 13-16, 1936. The examination covered 10 subjects and included 55 questions. An average of 75 per cent was required to pass. Six candidates were examined, 4 of whom passed and 2 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University School of Medicine.....	(1934)		80
Medical School.....	(1933)		84
School of Medicine.....	(1933)		79
University of Wisconsin Medical School.....	(1935)		86
School	FAILED	Year Grad.	Number Failed
Loyola University School of Medicine.....	(1936)		1
Licentiate of the Royal College of Physicians of London and Member of the Royal College of Surgeons of England.....	(1936)*		1

\* Verification of graduation in process.

### Georgia June Examination

Mr. R. C. Coleman, joint-secretary, State Examining Boards, reports the written examination given by the Georgia State Board of Medical Examiners in Atlanta, June 10-11, 1936. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Eighty-six candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....	(1932)		87.8
(1936) 83.8, 84.7, 85.3, 85.3, 85.5, 85.7, 86, 86, 86.6, 86.7, 86.9, 87, 87.4, 87.5, 87.6, 87.6, 87.7, 88, 88.4, 88.5, 88.7, 88.8, 88.9, 88.9, 89.1, 89.4, 89.6, 89.7, 89.8, 89.9, 90.2, 90.5, 90.7, 90.8, 90.8, 91.1, 91.3, 91.5, 91.5, 91.8, 92, 92.3, 93.8			
University of Georgia School of Medicine.....	(1936)		86.2
86.7, 86.9, 87.3, 87.5, 87.7, 88, 88.1, 88.3, 88.6, 88.6, 88.6, 88.7, 88.8, 88.8, 88.9, 89, 89.2, 89.3, 89.4, 89.7, 89.7, 89.7, 90.2, 90.2, 90.2, 90.2, 90.3, 90.4, 90.5, 90.5, 90.7, 91, 91.7, 91.8			
Rush Medical College.....	(1928)		93

University of Nebraska College of Medicine.....	(1934)	91.1
University of Rochester School of Medicine.....	(1935)	89
Meharry Medical College.....	(1936)	89.9

Thirteen physicians were licensed by reciprocity from February 6 through August 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
College of Medical Evangelists.....		(1932)	New Mexico
University of Colorado School of Medicine.....		(1930)	Colorado
University of Illinois College of Medicine.....		(1931)	Missouri
University of Louisville Medical Department.....		(1910)	Tennessee
Tulane University of Louisiana School of Medicine.....		(1923)	Louisiana
Western Reserve University School of Medicine.....		(1933)	Ohio
Jefferson Medical College of Philadelphia.....		(1911)	Penna.
University of Pennsylvania School of Medicine.....		(1934)	Penna.
Medical College of the State of S. Carolina (1933),		(1934)	S. Carolina
Meharry Medical College.....		(1935)	Tennessee
University of Tennessee College of Medicine.....		(1933)	Tennessee
Medical College of Virginia.....		(1930)	Virginia

## Book Notices

**Industrial Dust: Hygienic Significance, Measurement and Control.** By Philip Drinker, S.B., Ch.E., Professor of Industrial Hygiene, Harvard School of Public Health, and Theodore Hatch, B.S., S.M., Instructor in Industrial Sanitation, Harvard School of Public Health. Cloth. Price, \$4. Pp. 316, with 104 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1936.

Control of the dust hazard in industry is the joint duty of the physician and the engineer. On the whole, the engineer has done a better job than the physician. Two engineers at Harvard University, long and much experienced in industrial dust problems, have produced this praiseworthy book, covering almost every aspect of the problems of industrial dust in relation to the health of workers. The greater the familiarity of the reader with industrial dusts and dust diseases, the higher will be the appreciation of this excellent publication. Much of the material of this book represents first hand investigations of its authors. This, together with the work of other engineers and physicians, is well organized from the standpoint of the engineer. The scope of the field covered is reflected in chapters on the physical properties of dusts, fumes and mists, the effects of dusts and fumes on man, physical and chemical factors in pneumoconiosis, permissible dustiness, the dust survey, dust determination, determination of particle size, chemical and mineralogical analyses, control of the dust hazard, design of local exhaust systems, air cleaning apparatus, filtration, dust respirators and air masks. If patients with dusty lung diseases are to be kept out of hospitals, it is requisite that harmful dusts be kept out of the lungs of workers. This can be accomplished only at the work point. This book points the way to a full measure of dust control in industry. Since no less than two million workers daily are exposed to dusts of various types in the industries of the United States, the control of industrial dusts may not be regarded as a minor problem. This book may be accepted as a valuable guide in the eradication of a long existing and widespread evil in the United States.

**Fleber- und Infektionsheilerie: Ausgewählte Beiträge, 1887-1935, mit verknüpfenden und abschliessenden Bemerkungen.** Von Prof. Dr. Julius Wagner-Jauregg, gew. Vorstand der Psychiatr.-Neurol. Klinik der Universität Wien. Cloth. Pp. 299. Vienna, Leipzig & Berne: Verlag für Medizin, Weidmann & Co., 1936.

The author, now 79 years of age, well known for his successful introduction of malarial therapy for the treatment of neurosyphilis, presents the most significant of his publications on the subject of fever and infection therapy in this volume. There are eighteen selected papers (1887-1935), with an introduction and a conclusion. Each paper has a special comment attached which amplifies the information contained, adding greatly to the historical value of the book.

The first paper is a scholarly, painstaking effort to review in 200 cases the effects of infectious diseases on all the various types of psychoses. It tells of his early attempts in 1886 and 1887 to understand so-called spontaneous recovery from supposedly incurable diseases. It is noteworthy that dementia paralytica did not receive special attention, for although it had been known for more than a hundred years, its specific relation to syphilis was not conclusively demonstrated until 1913 by Hideyo Noguchi. Wagner-Jauregg believed that the cases showing the effects of infectious diseases on psychoses were

experiments of nature which should be brought under experimental control, so that clinical use could be made of the results. In the subsequent comment on the paper one learns that several psychotic patients (not with dementia paralytica) had been treated with streptococcus cultures from a patient with virulent erysipelas in 1888-1889 without success and hence a report had not been made.

The second paper, "Psychiatrische Heilbestrebungen," published in 1885, reviews again the facts and theories regarding the effect of infectious diseases on psychoses without attaining a clear understanding of the problem. It is enlightening, in retrospect, to follow the groping of the pioneer, unable to define the essentials yet determined that infectious fever therapy must be of some value. The comment following the paper mentions the use of old tuberculin following 1895 with specific selection of patients with dementia paralytica, principally because they never recovered without the intervention of an infectious disease, while patients with other psychoses occasionally recovered without any treatment. In 1900 the author treated sixty-nine unselected cases of dementia paralytica with tuberculin; the results published in 1904 by Pilcz showed undoubted benefit from the treatment in that life was prolonged and periods of remission were increased. Encouraged by this, every other patient with dementia paralytica was given a course of tuberculin and the results were compared with the controls.

The third paper, published in 1909, reports the favorable results obtained in treating private patients, whose disease was usually of shorter duration and who showed less deterioration, by tuberculin injections and simultaneous use of mercury and iodine. The following paper, published in 1912, reviews the advance of this therapy and discredits the efficacy of arsphenamine in dementia paralytica, for after 1905 arsphenamine had captured the stage and superseded all other methods of treatment.

The fifth paper, published in 1913, describes the fair success achieved during two and one-half years' trial of staphylococcus vaccine, which had been started in an effort to find a more efficient bacterial agent. Other vaccines also were tried. The sixth paper, published in 1914, reports encouraging progress with the tuberculin-mercury treatment, with a conviction that still longer remissions could be obtained by other as yet untried means.

The happy accident of having at his disposal a patient suffering from tertian malaria in June 1917 gave the author the opportunity to use the plasmodium as a means of artificially inducing fever. He had seen and heard of cases that showed favorable results following malaria and now found it superior to all other methods. He states that its superiority could not have been foreseen, since remissions had been obtained by other agents. The obvious hazard of malaria was a formidable barrier toward considering it a therapeutic agent, and there seemed great danger of spreading the disease. Numerous other pertinent questions of these dramatic times are discussed at length.

The following papers, published in 1918, 1924, 1926, 1927, 1929, 1933, 1934 and 1935, discuss technical problems and advances in the use of malarial therapy, including the treatment of the lancinating pains, the gastric crises and the optic atrophy of tabes, the types of malaria, the significance of blood grouping, the dangers of malarial therapy, the maximum improvements possible, and the mode of action. A paper published in 1934, on the use of short wave high frequency current, states that malaria is superior, since he believes that malaria has special immune body stimulating functions which probably are not duplicated by heat alone.

The last paper is a companion piece to the first two in that it reviews the field and furthermore makes an appeal to large mental hospitals to be more systematic in their treatment of psychoses with artificially induced fever. The conclusion surveys the great progress made and expresses hope for a wider use of pyretotherapy, which is already seen in multiple sclerosis and gonorrhea. He points out the real need for comparative studies between series of patients treated with malaria and those treated with diathermy, inductothermy, the Kettering air-conditioned cabinet, and so on.

This collection of papers will be of great interest to the student of the history of medicine and to the rapidly increasing number of those interested in pyretotherapy. This review of

a dramatic phase in the history of medicine furnishes encouragement for further careful clinical work in other diseases, when one remembers that the author worked at this problem for thirty years before he attained a satisfactory beginning.

**The Surgical Technic of Abdominal Operations.** By Julius L. Sprack, M.D., Assistant Professor of Surgery, University of Illinois College of Medicine. Cloth. Price, \$10. Pp. 718, with 677 illustrations. Chicago: S. B. Debour, 1936.

As the author states in the preface, the purpose of the book is not to replace apprenticeship but to render service in the study of the technic of operations on cadavers, on living animals, or by actual assistanceship. The subject is presented in a didactic manner, simple procedures being described first. A brief review of the evolution of the operations is offered in many chapters. A bibliography at the end of each chapter facilitates further studies. The text is to the point and is easily readable. The simplicity of the orderly presentation is worthy of praise. The illustrators deserve special commendation. Exceptions may be taken to certain omissions and commissions. A scientifically trained physician is or should be familiar with the metric system, and the latter should be used exclusively in the manuals. The impression may be gained that degastro-enterostomy, i. e., undoing a previously made stoma, is the only method of dealing with postoperative gastrojejunal ulcer, while in reality more complicated procedures are frequently unavoidable. For didactic purposes it might be desirable to designate the Billroth I, Billroth II and Polya operations as an end-to-end, side-to-side and end-to-side anastomosis. "Cholecysto-electrocoagulectomy" is not only a tongue twister but a misnomer, as it implies the removal of a coagulum; there should be a limit to attempts of describing a procedure in one word. Devoting seven pages to a description of splenectomy and only three pages to the technic of splenectomy must be considered as an incongruity. Kocher's method of repair of a hernia and the use of living sutures or fascia strips are not mentioned. On page 664 the word "adnexa" appears with the spelling "adnexae." Gynecologic operations have been treated in a cursory manner; emphasis should be laid on the knowledge of the topography of the ureters. This little adverse criticism may be justifiably offered but should not detract from the value of the book, which undoubtedly will meet a heartfelt approval by every undergraduate and postgraduate student.

**La pratique du pneumothorax thérapeutique.** Par F. Dumarest, P. Lefèvre, H. Mollard, P. Pavie et P. Rougy. Préface de Fernand Bezançon. Fourth edition of "La pratique du pneumothorax thérapeutique," by F. Dumarest and Ch. Murard. Paper. Price, 50 francs. Pp. 474, with 345 illustrations. Paris: Masson & Cie, 1936.

This excellent volume on pneumothorax therapy pays high tribute to Carlo Forlanini and carries a frontispiece portrait of this pioneer of pneumothorax, with an elucidating preface by Prof. Fernand Bezançon. A thirteen page historical introduction paves the way for a better understanding of the main text, which has been brought down to date by new revisions. The text is appropriately presented in fifteen chapters covering all phases to a full understanding of the mechanism, procedures and results of collapse therapy. Where required, theories are presented and appropriately dispensed. The first edition was presented in 1918, and the authors close the present edition with a part of the introduction of the first edition calling attention to the proper performance of the procedures outlined to attain success, and point to the inestimable value of the procedures for treatment if properly performed. Imprudence can only lead to danger in spite of favorable existing conditions. Radiologic control is considered indispensable. Pneumothorax is credited as a most valuable agent in phthisiotherapy. Some students of this subject might object to the oversteering of the Forlanini ideas and methods at the expense of numerous other contributors to the subject, but this can be readily overlooked as a result of the generous practical information given. In sequence, the subject matter presents the physiomechanics of the lungs and the principles of collapse therapy with the mode of action of pneumothorax and the methods of collapse. Then follow the various types and parts of the equipment, with the technic used and the accidents to be encountered, such as cardiac and nervous complications, subcutaneous emphysema, gas embolism and pleural eclampsia. Under monolateral pneumothorax is considered the primary filling with the significance

of manometric readings, the intervals for filling, the quantity of gas and the period for pneumothorax. The symptoms of pneumothorax are elucidated with and without the presence of adhesions, and hernia of the mediastinum, elective pneumothorax and the immediate results such as fever and cough are described. The influence on the opposite lung and the effect on intercurrent diseases are noted. The pleural complications of pneumothorax with pathogenesis, and clinical interpretations are well presented without omitting any details to a full understanding of the prognosis and treatment, both medical and surgical. The recently developed subject of oleothorax with its technic, indications and complications form an interesting chapter. Several chapters are devoted to the anatomic pathology of the collapsed tuberculous lung and to the mode of action of pneumothorax on the tuberculous disease. The indications and contraindications of monolateral pneumothorax are considered from various angles, including the form and character of evolution of the lesions, the age and sex of the individual, the relation to spontaneous pneumothorax, empyema, pulmonary gangrene, bronchiectasis, hydatid cysts, traumatic hemothorax, pneumonia and bronchopneumonia, the general condition, the heart and circulatory system and the nervous system. In the final chapters the entire subject of pneumothorax is rounded out by consideration of simultaneous and alternating bilateral pneumothorax in its various phases, with an elucidation of pleuroscopy with the endopleural liberation of adhesions. As complementary methods to pneumothorax are given phrenicectomy, scalenotomy with intercostal paralysis, and finally the addition of thoracoplastic operations, partial or complete. The shortcomings of the volume, if there are any, are overshadowed by the practical material presented. The main drawback for the American physician is the fact that it is entirely in French, but for those who read French fluently there is no substitute for this book in the English language; and it might well merit consideration for an English translation. It is intended to cover the practice of pneumothorax as a collapse procedure which deserves the attention of physicians in general and the chest specialist in particular. The volume is paper covered and printed on a good grade of paper, and illustrations are ample but not profuse, line drawings replacing roentgenograms and probably advisedly so, since this is not a roentgenographic textbook and does not detail case reports. It is a well worth-while volume developed over two decades by a group conversant with the subject and recommended by Bezançon, professor of the tuberculosis clinic of the Laennec Hospital, attesting its good quality. Bezançon points out that the use of pneumothorax developed as the fruit of a rational physiologic conception and not by accident. So, likewise this volume is full of rationalities.

**Music in Institutions.** By Willem van de Wall, Doctor of Music, Teachers College, Columbia University. Assisted by Clara Maria Ljepmann, Doctor of Jurisprudence. Cloth. Price, \$3. Pp. 457, with 15 illustrations. New York: Russell Sage Foundation, 1936.

The author of this opus gives this as his main theme: "This book is written to bring to the attention of public minded citizens, especially those interested in welfare institutions, ideas and suggestions about the use of music . . . as an organic detail of institutional life and treatment, and planned to meet the inmate's need for social adjustments and integration of his personality." He then proceeds to develop this theme, presenting a deal of experience, theoretical consideration and practical information in the field of music as an aid to those sick in body, mind and morals immured in institutions. Dr. van de Wall is well qualified for this work through years of toil in his chosen specialty. After reading the endeavors of the author, one gathers that the way in which music is presented in many institutions housing the ailing is haphazard and inadequate and does not reach its main purpose as outlined in the book. In fact, many effects not obtained now are possible if a more studied and systematic application of music is made to those receptive to this mode of approach. With whatever statistics are available at present, no honest observer would claim that music alone cured a patient with dementia praecox, reformed a confirmed criminal or raised the native intelligence of a moron. Shorn of all piffle, it must be admitted that there is little if any potency in the so-called music therapy as administered today. In the main, music is still purely recreational or diverting and does a great deal if it ameliorates the con-

dition of the ailing by giving pleasure or relieves the tedium of a prolonged incarceration or keeps the emotions in some sort of control. But if there is talk of bringing a psychotic patient back to reality by means of music alone there is need for closer investigation behind the smoke screen of premature enthusiasm. There are so many other activities as a part of the life of the institutional inmate that the precise value of music as an isolated therapeutic measure is difficult to estimate, especially in the case of the insane, in which it is supposed to find its greatest usefulness. Then too the temperament, culture and idiosyncrasies of patients must be carefully studied before music as a medical means can be successfully applied. If the objective is to make music a definite therapeutic asset, better methods must be invented that will judiciously correlate music with personality. It is then only that music therapy as a scientific approach can be properly evaluated. The sane and sober exposition of Dr. van de Wall is encouraging. The volume is highly recommended to progressive physicians and musicians and to recreational therapists as the best handbook on music and the dance for institutional work extant. The material is well arranged, clearly written and illustrated. There is an extensive bibliography and the volume is well indexed.

**The Nature and Treatment of Asthma, Hay Fever and Migraine, with Other Clinical Studies on Pyrogenic Therapy, Oxygen Want, Examination of Chest, Chronic Bronchitis, Pneumonia, Protracted Resolution, Fibroid Pneumonia, Pulmonary Apex, Roentgen Rays, Recovery from Subacute Phthisis, Fibroid Phthisis, Phenolsulphonphthalein, Acute Nephritis, Functional Albuminuria, Renal Oedema, Etc. Original Investigations.** By Alexr. Gunn Auld, M.D., Diplomate in Public Health of the University of Oxford. Cloth. Price, 12s. 6d. Pp. 257, with illustrations. London: H. K. Lewis & Co., Ltd., 1936.

The volume consists almost entirely of articles previously published by the author, dating from 1885 to 1936. It may be divided into two parts. The first half deals with the peptone treatment of asthma. Little is said about most of the other aspects of the disease. The usual rôle of allergy in the etiology of asthma and the importance of its consideration is lightly swept aside by the insistence of the author that nonspecific desensitization with peptone is the only diagnostic-therapeutic procedure required. With regard to pollen therapy in hay fever he concludes that "the peptone treatment may be given quite alone, with as good results." The second half of the book deals with such a variety of subjects as chronic bronchitis, a case of recovery from subacute phthisis, renal edema, remarks on the picric acid test and a case of hystero-epilepsy. It is difficult to imagine what purpose this volume could serve to the student, practitioner or specialist. It is pathetically incomplete and biased on the subject of allergy. The general obsolescence of the information on the other diverse topics discussed could leave only one possible function for this volume; that is, to serve as a historical record of the life work of a practitioner, which may be an interesting memento to his admirers.

**New Faces—New Futures: Rebuilding Character with Plastic Surgery.** By Maxwell Malitz, M.D. Cloth. Price, \$3. Pp. 315, with 74 illustrations. New York: Richard R. Smith, 1936.

The author, who has been a frequent contributor to lay publications, wields a facile pen and succeeds ably in glorifying and dramatizing plastic surgery for the nonmedical reader. The book combines historical references, quotations, anecdotes and sufficient suggestions as to technic in an impressive manner so that there is no doubt that for the uninformed it should possess a tremendous appeal. However, the chapter on drama in the operating room, though doubtless effective for the layman, is nevertheless a bit too reminiscent of movie technic to be quite consistent with professional dignity. The principal burden of the discourse is the psychologic aspect of facial blemishes or disfigurements and the astonishing changes in temperament and outlook on life that result from their correction. Numerous case histories are cited by way of illustration. The author, however, fails to mention the discomfort, pain, anxiety and occasional disappointment which frequently accompany these operations, so that one might gain the impression that they are always successful. Also he misses an opportunity to draw the distinction between true deformities and those which are purely imaginary, the latter constituting a considerable percentage of the patients who plague the plastic surgeon and go from one to another seeking the impossible. Nevertheless the author does

the profession a good turn by emphasizing the difference between the reputable qualified surgeon and the quack and by suggesting that the prospective patient make inquiry of the American Medical Association or the local medical society for information on this extremely important matter. The chapter on the rehabilitation of the criminal through the correction of facial deformities such as pug nose, cauliflower ears and disfiguring scars, as suggested by Commissioner MacCormick of New York, affords food for thought even though at first blush the proposition seems fraught with danger. The craze for beauty parlor treatments, the multiplicity of skin lotions and creams and the inordinate habit of "facials" all come in for proper criticism and are sensibly debunked in a chapter on the skin and cosmetics.

**Elementary General Psychology.** By Samuel W. Fernberger, Professor of Psychology, University of Pennsylvania. Cloth. Price, \$3. Pp. 445, with 120 illustrations. Baltimore: Williams & Wilkins Company, 1936.

This book, which is intended for the beginning student, is excellent in many respects. As the author states, it is intended to give the student a first orientation in the material of the science of psychology. As such, it fills the purpose better than most books of its kind. It is preeminently a textbook in experimental psychology, and those chapters which deal with the simpler conscious processes, that is, the special senses, are particularly good. However, in the first page of the preface the author says "Confession must be made that I am an old-fashioned psychologist" and unfortunately modern advances in the understanding of psychologic processes are almost entirely ignored in this book. Freud's concept of the "unconscious" mind is dismissed with a short reference on page 35 and seven pages near the end of the book. The writer shows an almost complete ignorance of psychoanalytic concepts and of Freud's writings. He completely confuses the work of Freud, Adler and Rank, refers to the latter two as psychoanalysts, and consistently uses the term "subconscious" rather than unconscious to explain the freudian concept of a dynamic psychology. The pages devoted to psychoanalysis as a technical procedure are ridiculous. The only reference to the "unconscious mind" is contained, peculiarly enough, in the last paragraph of the preface, in which the author says "I have no idea how much unconscious plagiarism there may be in these pages"; so that while practically denying, or at least minimizing the psychologic importance of an unconscious mind, he confesses to its existence in himself.

**Berättelse från styrelsen för cancerföreningen i Stockholm över verksamhetsåret, 1935. Index of Papers Published at the Radiumhemmet 1909-1935. Report on Cases Treated at the Radiumhemmet 1921-1935.** [By Ellis Beren and Jones Heyman.] Paper. Pp. 104. Stockholm: K. L. Beckmans Boktryckeri, 1936.

The first part of this report gives an account for 1935 in Swedish of the management of the cancer society in Stockholm. Then comes a list of the papers published from Radiumhemmet since its foundation in 1909. The remaining fifty-four pages contain a statistical analysis and summary of the cases treated at Radiumhemmet from 1921 to 1935. Like the previous report, this report also is of interest to all who are concerned with the modern treatment of cancer.

**Trudy pervogo ukrainskogo s'ezda nervopatologov i psikhiatrov. Otvetsvennyy redaktor: L. L. Rokhlin. Otvetsvennyy sekretar: O. I. Volfvskiy. Travaux de la première réunion ukrainienne des neuropathologues et aliénistes. Cloth. Price, 19 rubles, 50 kopecks. Pp. 928. Khar'kov: Izdanie Ukrain'skoy Psikhonevrologicheskoy Akademii, 1935.**

The program included the problems of organization of psychoneurologic practice, of infections of the nervous system, and of psychiatry. Each paper is accompanied by a summary in English and in French. The size of the volume and the variety of subjects preclude the possibility of a detailed review.

### CORRECTION

**The Extra-Ocular Muscles.**—In the review of the book by Luther C. Peter with this title, the first sentence read "In 1920 there appeared in these pages a review of the first edition of Peter's Muscles, and now after sixteen years a second edition has been published." This statement was in error. The first review of the book appeared in 1927 and the lapse of time between the first and second editions was not sixteen years but nine years.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice: Gangrene Attributed to Tight Casts.**—Lundgren sustained a fracture of the tibia and fibula of his right leg approximately at the juncture of the lower third of the leg with the middle third. Eventually gangrene developed and an amputation became necessary. Attributing the gangrene to the negligence of the defendant in applying the casts, the plaintiff sued and obtained judgment in the lower court. The defendant thereupon appealed to the Supreme Court of South Dakota.

According to the evidence the plaintiff, twelve hours after the accident, was brought to a small hospital, where a physician applied a dressing and put the leg in "some kind of a splint." He remained in this hospital for about a week and was then removed to another hospital, where the defendant assumed charge of the case. Roentgenograms disclosed that the broken bones were not in apposition and an open reduction was done. A considerable amount of gas and pus escaped and the incisions were left open and drainage tubes were inserted. A "Boehler splint" was applied and hot dressings were used on the leg from the knee down. The patient's general condition was treated for a number of days. Two weeks later another operation was performed and a "cow-bone splint" was applied. The leg was placed in a plaster cast extending from some distance above the knee down to the toes. Windows were cut in the cast to permit access to the incisions made on May 15, and to the field of drainage therefrom, and to relieve pressure around the heel. These windows were later enlarged. On June 11, a "massive hemorrhage" occurred from the wounds on the patient's leg, which the defendant attributed to a partial destruction of the posterior tibial artery due to the infection that had developed in the leg. About a month later the cast was removed. Another roentgenogram indicated a little growth of new bone above the point of fracture but no new growth below and, in fact, some deterioration of bone tissue. The leg was placed in an open wire cradle for five days and then a second plaster cast was applied. On August 24, about a month later, the second cast was removed and another roentgenogram showed further growth of new bone above the point of fracture but still further deterioration of bone structure below the fracture. On August 30 the patient dismissed the defendant and called in another physician, who found the patient's foot in a gangrenous condition. After taking measures to improve the patient's general condition, he amputated the leg midway between the hip and the knee.

The plaintiff contended that the gangrenous condition of his foot necessitating the amputation was due to impaired circulation resulting from too tight application of the casts. The defendant contended, on the other hand, that the leg was badly infected in the area of the fracture when he first saw the plaintiff and that the gangrene was due to the destruction or partial destruction of the posterior tibial artery by that infection, thereby impairing the circulation of blood to the foot. The physician who operated testified that the condition of the foot when he saw it was not the condition that he would have expected to find if the proximate cause thereof had been a breaking down of the posterior tibial artery, and that a cast unduly tight and constricting could have caused the condition. The plaintiff testified that almost immediately after the first cast was applied, symptoms of undue constriction appeared, that he complained to the defendant and to the nurse that the cast was too tight, that his toes were swollen, discolored and painful and that a sore or ulcer appeared on his heel. The condition of the foot improved after the first cast was removed, he testified, but grew worse after the second cast was applied which was even tighter than the first one. He continuously complained about the discomfort it caused.

The injury in this case, observed the Supreme Court, was to a part of the body not being treated. The treatment was for a fracture a little below the knee. Gangrenous destruction of the foot is not a normal or usual result of such a fracture.

It is a result that might very well follow if the casts were permitted to be or remain so tight as unduly to restrict circulation in the foot. Certainly where, as here, the toes were at all times observable, to permit a cast to remain too tight would be either unskilful or negligent, or both. Even though the defendant exercised good judgment, said the court, with respect to how tight the casts should be when he put them on, that fact would not excuse him from carefully watching conditions thereafter and loosening the casts if there were indications either that they had been put on too tightly or that because of swelling of the leg they had subsequently become unduly constrictive. If the jury believed the plaintiff's testimony, said the Supreme Court, they would be justified in finding that the destruction of the foot resulted from the casts being too tight. If the jury accepted the testimony of the defendant and his witnesses, they would be justified in believing that the casts never were tight and that the impairment of circulation and consequent destruction of the foot resulted from the breaking down of the supplying artery due to infection. The real point at issue was one of fact rather than medical theory or expert opinion. It was for the jury to determine whether the gangrenous destruction of the foot resulted from impairment of circulation by reason of the breaking down of the artery, for which the defendant would not be liable, or whether it resulted from the defendant's lack of care or skill, or both, in incasing the injured leg in casts too tightly applied and maintained, for which the defendant would be responsible.

After reviewing the entire record, the Supreme Court did not feel it could disturb the findings of the jury. The judgment in favor of the plaintiff was accordingly affirmed.—*Lundgren v. Minty (S. D.), 266 N. W. 145.*

**Workmen's Compensation Acts: Employee's Right to Procure Additional Medical Care When That Furnished by Employer Is Inadequate.**—The claimant, a nurse in the Los Angeles County General Hospital, contracted poliomyelitis in the course of her employment. She was admitted to the hospital for treatment, June 5, 1934. Because of crowded conditions due to an epidemic of poliomyelitis, she was apparently unable to obtain the care which her condition required. Sometime after June 28 she developed a mental condition bordering on psychosis. At the instance of a former intern at the hospital, following a conference with the resident physician and a physician in charge of industrial accident cases for the county, she was transferred to a hospital at Mecca and later to another institution. She made steady improvement. From time to time bills for her treatment were sent to the Los Angeles County General Hospital, which the county refused to pay. On Feb. 5, 1935, the claimant was returned to the Los Angeles County General Hospital. Her condition at that time was much improved but became worse after a short stay in the General Hospital and her previous symptoms manifested themselves again. On March 11, 1935, the proper county officials ordered the claimant transferred to the Mecca hospital and authorized the payment of bills for her treatment from that date on. Subsequently, the claimant was awarded compensation by the California industrial accident commission, which award included an amount sufficient apparently to pay all bills for her treatment. Los Angeles County, her employer, then brought certiorari in the district court of appeal, second district, division 1, California, to review the award, contending that since it had not authorized the claimant's removal, in the first instance, to the Mecca hospital or to the other institution, it was not liable for the charges of the two institutions for her care and maintenance.

Section 9 (a) of the California workmen's compensation act, as amended, makes it the duty of the employer to provide—such medical, surgical and hospital treatment, including nursing . . . as may reasonably be required to cure and relieve from the effects of the injury, the same to be provided by the employer, and in case of his neglect or refusal seasonably to do so, the employer to be liable for the reasonable expense incurred by or on behalf of the employee in providing the same.

If, said the district court of appeal, the treatment supplied by the employer does not within a reasonable time effect a cure, and if the employee thereafter obtains different treatment from his own physician which does seasonably benefit or cure him, he has established the inadequacy of the treatment previously

tendered by the employer, and is justified in changing to his or her own physician, for whose services the employer is liable. 71 C. J. 780. There was evidence before the commission that the treatment received by the claimant at the county general hospital was not such as would seasonably or adequately cure and relieve her from the effects of poliomyelitis and that the treatment to which she resorted did benefit her. Furthermore, said the court, when the claimant became worse after her return to the Los Angeles County General Hospital, the board of supervisors of the county ordered that authority be given for her transfer back to the Mecca hospital for treatment. This action admitted the inadequacy of the treatment at the County General Hospital and conceded the beneficial results that had accrued from her prior hospitalization at the Mecca hospital. Under the circumstances, concluded the court, the claimant had a right to procure medical and hospital treatment other than that tendered by the employer, and the employer was liable for the expenses thereof. The award was therefore affirmed—*Los Angeles County v. Industrial Accident Commission (Calif.)*, 56 P. (2d) 577.

**Malpractice: Pulmonary Abscesses Allegedly Due to Aspiration of Tooth During Tonsillectomy.**—One of the appellants, a physician, performed a tonsillectomy on a 10 year old boy at the Hazard Hospital. The next day the child was removed to his home and was thereafter placed under the care of the family physician. That evening he became ill and his condition was diagnosed as bilateral bronchial pneumonia. About four weeks later he was well enough to return to school but at the end of ten days he again became ill and had an elevated temperature. A roentgenogram taken at the hospital was interpreted by the roentgenologist as showing acute pulmonary tuberculosis. About a month later the child coughed up a tooth. The child eventually died as the result, apparently, of pulmonary abscesses, and the plaintiff, the child's administrator, sued the hospital and the operating physician, contending that the tooth had been negligently loosened during the operation. From a judgment in favor of the plaintiff, the defendants appealed to the Court of Appeals of Kentucky.

The child's parents testified that immediately after their son had come out from under the influence of the ether, about one hour after the operation, he said "Mother, the doctor pulled one of my teeth," that they examined the child's mouth and found that a tooth was missing, and that his gum was bleeding as if the tooth had been recently pulled. A nurse, however, who was the only other person in the room, denied that the child ever made such a statement or that any one had discovered a tooth missing. The physician testified positively that the tooth was not dislodged during the operation and that the mouth gag used was of the standard make and was handled in the usual and ordinary manner. His testimony was corroborated by that of the anesthetist and the surgical nurse. The medical testimony was in accord that ether pneumonia frequently follows the administration of ether anesthesia, and that mucous or other foreign materials may be breathed into the lung following a tonsil operation, which, if infected, may cause abscesses in the lung. The abscesses in the instant case, according to the medical testimony, may have been due to the presence of the tooth in the lung or may have been due to the aspiration of blood and mucus.

The record, in the opinion of the court, was devoid of any facts justifying an inference that the child's tooth was knocked out during the operation. Assuming that the tooth was actually in the child's lung and accepting the testimony of the child's parents that the tooth was found to be missing following the operation, there was no evidence that the tooth was negligently knocked out during the operation. It may have simply fallen out of its socket. The burden was on the plaintiff to prove that the injury complained of resulted proximately from want of care. Proof of a bare possibility that the injury might so have resulted will not suffice. The plaintiff further contended that the defendants could have discovered the tooth in the decedent's lung in time to have removed it and to have saved his life, but negligently failed to do so. But, said the court, all the physicians interpreted the roentgenograms as indicating a tuberculous condition. The most that could be said is that they were mistaken in their judgment, and an error of judgment does not constitute negligence.

The Court of Appeals concluded that the trial court should have instructed the jury to return a verdict for the defendants. Accordingly, the judgment for the plaintiff was reversed.—*Hazard Hospital Co. v. Combs' Adm'r (Ky.)* 92 S. W. (2d) 31.

**Evidence: Conclusiveness of Medical Testimony.**—The appellee's wife applied to the appellant insurance company for a life insurance policy without medical examination, stating, apparently, that she was in good health. The policy was issued June 1, 1934. The insured died July 12, 1934, as the result, apparently, of cancer of the pelvic region. The insurance company refused payment claiming the insured had misrepresented, in her application, the state of her health. The husband, and beneficiary, obtained judgment in the district court and the insurance company appealed to the court of civil appeals of Texas, Amarillo.

Three physicians, who had examined the insured after the application was signed and apparently before the policy had been issued and delivered, testified that she had cancer. One of the physicians testified that in addition to the cancer he found a fistula through which the contents of her small intestines were passing into and were being discharged through the vagina. There was, however, no medical testimony as to her condition at the time the application was signed. The insured's husband, the appellee in this case, and four lay witnesses testified that except for four or five days preceding her death the insured had not been ill, had continued to perform her usual household duties including washing, cooking and taking care of the children. The trial court did not err, said the court of civil appeals, in permitting the appellee's counsel to inform the jury that it was the judge of the weight of the testimony and the credibility of the witnesses, and that it could believe or disbelieve any witness in case the evidence was conflicting. A jury, said the court, is not bound to accept the testimony of expert witnesses as true. The opinion of an expert is entitled to only such weight as the jury may see fit to give it, and the opinions of physicians concerning the insured's health at the time the policy was issued were not conclusive. When, as here, continued the court, the verdict is based on conflicting evidence, it will not be disturbed in the absence of legal error. If the evidence is sufficient to justify the verdict, it will not be disturbed even though the reviewing court might reach a different conclusion and even though it appears to be against a preponderance of the evidence.

The judgment of the trial court for the appellee was consequently affirmed.—*Universal Life & Accident Co. v. Nanes (Texas)*, 92 S. W. (2d) 473.

## Current Medical Literature

### AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Requests as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Simple Slide Test for Syphilis.**—Lewis devised a modification of the precipitation reaction. He has tested 1,500 serums from prospective transfusion donors with this test when rapid results were necessary. In no instance has the test been strongly positive when the Kolmer, Kahn and Kline were negative. In treated syphilis all the standard precipitation technics and his have proved somewhat more sensitive than the Wassermann reaction. Into a small test tube, 0.1 cc. of stock antigen and 0.3 cc. of the saline diluent are measured. The tube is shaken for a moment and mixed thoroughly for a few seconds by means of a capillary pipet with a rubber bulb or a medicine dropper. The mixture is allowed to stand for five minutes and is agitated again just before using. The antigen mixture should be used within thirty minutes of its preparation. Two drops of clear serum that have been heated at 56 C. for thirty minutes are placed on a slide, and adjacent to the serum three drops of the antigen mixture. This is mixed with the broader flat end of a toothpick so that the mixture occupies the middle two thirds of the slide and is not near enough to the sides to run over. The slide is rocked from side to side for three minutes and read within five minutes by indirect light against a dark background, or by holding a daylight bulb in front of and just above it. The test should not be performed in a cold room, as this causes a tendency toward false positives. Fans and strong drafts should be avoided. Negative serums have a smooth, cloudy, opales-

cent appearance. Positive serums show various degrees of a brownish granular precipitate, easily seen. Very strongly positive serums will show large clumps floating in an almost clear fluid. A minute amount or degree of precipitation should be disregarded or checked by other methods.

#### Hippuric Acid Excretion as Test of Hepatic Function.

—Kohlstaedt and Helmer used the hippuric acid test in seventy-seven cases. The results indicate that there may be a marked reduction in the detoxifying ability of the liver before any of the clinical signs of hepatic disease can be detected. The simultaneous determination of the urea clearance increases the value of the hippuric acid test. The ether extraction method with the formol titration is the most practical as well as the most accurate method of determining the hippuric acid in the urine. The combined urea clearance and hippuric acid test is a reliable and valuable adjunct in the study of hepatic disease.

#### Relation of Gastric Acidity to Erythrocyte Blood

Count.—Apperly and Cary studied the relation of gastric acidity to the red cell content of the blood in normal persons, in hemorrhagic anemia and in polycythemia. They made experiments on anemia and polycythemia in dogs, observed the incidence of achlorhydria in anemia and polycythemia and the relation of gastric acidity to the red cell content of the blood in association with gastric abnormality. Their observations show that: 1. When, as a result of recent or chronic hemorrhage, the red cell content of the blood falls below a certain critical level, free acid disappears from the stomach. Their results in a few cases in man indicate that this level is, on the average, about one-third to two-thirds the normal. In dogs the critical level is much lower. They have no information concerning gastric acidity in anemias of other origins. 2. Above this critical level, gastric acidity rises with the erythrocyte content to a maximum when the latter somewhat exceeds that found in normal health; i. e. in man, a hematocrit volume of 46 per cent. 3. With increasing hematocrit volumes above about 50 per cent in man and the dog, acidity steadily falls again to low figures. 4. From the foregoing a rising incidence of achlorhydria should be expected with increasing anemia and increasing polycythemia. This has been shown to be a fact by several observers. 5. When severe hemorrhagic anemia is associated with peptic ulcer, pylorospasm or certain other gastric conditions, acidity values are found to be far higher than those with a corresponding degree of anemia without gastric abnormality. 6. The experiments show that in certain conditions when anemia is associated with achlorhydria, the entity anemic achlorhydria must be considered in addition to Witts's achlorhydric anemia and pernicious anemia.

## Viability of Parasitic Protozoa After Death of Host.

—The results of Hegner's studies involve intestinal protozoa in rats, guinea-pigs and frogs, malaria parasites in birds and trypanosomes in rats. He found that trichomonad flagellates may remain alive and multiply when transferred to suitable mediums after being in the cecum of a dead rat at 37 C. for twenty-four hours, at room temperature for four days and at 5 C. for thirteen days. Balantidial ciliates may remain alive in the cecum of a dead guinea-pig at room temperature for four days and at 5 C. for four days. Intestinal protozoa may live for from two to twenty days or more in a dead frog. The ciliates appear to be less resistant than the flagellates. *Opalina* lived for at least four days, *Nyctotherus* for nine days, *Trichomonas* for seventeen days and *Hexamita* for twenty days. *Plasmodium cathemerium* remained alive and capable of infecting clean canaries after being in the blood of a dead canary at 5 C. for forty-eight hours. *Trypanosoma lewisi* remained alive in the body of a dead rat for three days at room temperature and for ten days at 5 C. They were capable of infecting clean rats after nine days in a dead rat at 5 C. An attempt was made to demonstrate the failure of the trypanocidal antibody to appear at the peak of the infection in the dead rats, but the conditions of the experiment rendered the data unreliable.

**Antibodies for Influenza Virus.**—Brown performed influenza virus (Puerto Rico 8 strain) neutralization tests using mice, with the serums of persons with various histories of attacks of influenza with the following results: 1. Neutralizing antibodies were present in the serums of 74 per cent of the adults who had influenza during the 1918 and 1919 pandemic but who have not had the disease since that time. 2. Adults who passed through the 1918 and 1919 pandemic and subsequent seventeen years without an attack of influenza possessed potent antibodies to the Puerto Rico 8 virus. 3. The incidence of antibodies to the Puerto Rico 8 strain of influenza virus of children from 3 to 12 years of age was approximately the same as their incidence in the adults tested. Such antibodies were encountered infrequently in children less than 3 years of age. 4. Neutralizing antibodies to the Puerto Rico 8 virus in the serums of persons convalescent from an illness diagnosed sporadic influenza were no more potent than the antibodies present in their serums previous to the disease. 5. Attempts to

recover a filtrable virus pathogenic for ferrets from three persons diagnosed as having influenza during a small institutional epidemic all failed. Neutralization tests in mice with the serums obtained from these patients during their illness and also after their convalescence indicated that no appreciable change had occurred in their antibody content to the Puerto Rico 8 strain of influenza.

**Effect of Mediums on Activity of *Endamoeba histolytica*.**—The present observations reported by Frye and Meleney indicate that the decrease of pathogenic activity of *Endamoeba histolytica*, when washed cultures are suspended in horse serum-Ringer's solution (1:6) for inoculation into kittens, is not due, as they previously stated, to the absence of bacteria in the suspending medium, but seems to be due to an inhibiting effect exerted by horse serum. This is shown by the fact that Ringer's solution alone as a suspending medium did not exert the inhibiting effect shown by horse serum-Ringer's solution. Boiled horse serum-Ringer's solution not only did not show the inhibiting effect of fresh horse serum but seemed to stimulate the amebas to somewhat greater pathogenic activity. Berkeley filtrates of the supernatant fluid of the ameba culture, when heated to the point of coagulation of albumin (70 C. or higher) and used as suspending mediums for washed amebas, resulted in a considerable increase in the pathogenic activity of the amebas. The phagocytosis of red blood cells by washed amebas in vitro was most marked in heated filtrates, somewhat less marked in boiled horse serum-Ringer's solution, still less in horse serum-Ringer's solution, and poor in Ringer's solution alone.

**Trichomonas Vaginalis Vaginitis.**—Allen believes that high dry magnification of the fresh unstained vaginal secretion under reduced illumination simplifies the diagnosis of *Trichomonas vaginalis* vaginitis. Later staining of the dried secretion will serve to differentiate the other common forms of vaginal infection, such as yeast and gonorrhea. The profuse bubbly discharge found in this condition is laden also with various strains of streptococci. These streptococci may invade the urinary tract, Bartholin glands and probably the deeper structures of the pelvis. In like manner the male urinary tract may become infected during coitus either with the coccoid organisms or the motile flagellates themselves, and a troublesome urethritis or prostatitis is the result. Constant reinfection of the female renders permanent cure impossible until the male focus has been treated. Permanent cure of *Trichomonas* vaginitis will depend on recognition of possible avenues of infection. Elevation of the general resistance of the patient is important in the therapy. Scrubbing of the vaginal walls should not be instituted until some of the acute reaction has subsided. The vaginal walls are then sprayed uniformly with the powder proposed by Gellhorn (two parts of acetarsone to seven parts each of kaolin and sodium bicarbonate). The introduction of the powder can be accomplished readily by the use of the small blower used for insect powders. The excess powder may be kept in the vagina by inserting a pledget of cotton between the blades. The external genitalia also should be dusted with the powder. This treatment should be done daily for at least six days and should be reinstituted for a few days following the next menstrual period. In the interim the patient is instructed to insert into the vagina nightly a vaginal suppository containing 1 per cent of trinitrophenol, followed in the morning by a 2 quart warm water douche to which has been added 1 teaspoonful of lactic acid. The frequency of these topical applications should be decreased as the vaginitis improves, but they should be persisted in for at least three months. If the symptoms do not disappear rapidly or at any time the patient complains of vulvar irritation, the treatment is changed. A tablet containing the same ingredients as the powder may be substituted for the suppositories. Carbarsone may be substituted for the acetarsone in either the powder or the tablets. Tampons soaked in the broth filtrate as described by Hibbert may be substituted for the insufflations of powder. A 10 per cent solution of strong protein silver introduced into the vagina with the patient in the knee-chest position will often produce gratifying results.

**Puerperal Cervix.**—Barrett quotes Miller and his associates to the effect that a damaged or diseased cervix is present in 80 per cent of all women who have borne children. Cervical erosions, cervicitis and endocervicitis are known to exist in about 10 per cent of nulliparous women. Evidence has accumulated showing the frequency with which these diseased and neglected cervixes lead to puerperal infection in subsequent labors. A chronically diseased cervix bears a direct relationship to malignant conditions in this area. Adequate postpartum and puerperal care of the cervix properly begins at the first antepartum examination of the patient. The examination includes the usual smears for bacterial flora and, in addition, inspection to reveal lacerations, cystic changes, polyp growths, erosions, granulations and epithelial changes, such as leuko-

plakia. The use of the colposcope is helpful in the detection of any surface changes or irregularities. Any areas with a loss or change of normal epithelium should receive special scrutiny. Malignant conditions having been excluded and all acute infection cleared up, the chronic lesions, such as erosions, cervicitis, cystic changes and endocervicitis, should receive proper treatment. In the majority of instances these conditions may be eradicated by some form of electrosurgical diathermy, such as the Hyams conization method or simple electrocoagulation. These methods are suitable for office treatment. In the more extensive lesions of the cervix, surgical correction by Sturmdorf or Emmet trachelorrhaphy may be preferable. Electrocoagulation may be used to clear up common cervical lesions in the early months of an existing pregnancy. There is a slight danger of interrupting pregnancy, however, and the patient should be warned of this possibility. Trauma to the cervix must be avoided during labor so far as is possible. At the end of the third stage of labor, under strict surgical precautions, the cervix should be palpated and inspected. Lacerations of various types may be present from simple avulsion of the muscle fibers or nicks in the mucosa to the true unilateral, bilateral or stellate lacerations of varying depth and extent. If unrepaired, these lacerations tend to heal slowly by granulation with an increased scar formation, infection, hypertrophy and eversion of the cervical lips. If lacerations of 1 cm. or more in depth are found, these are immediately sutured. Healing is more prompt and complete if the mucosa of the cervical canal is not included in the suture. Primary repair of cervical lacerations should not be undertaken in the presence of shock or after an exhausting labor, or in cases in which infection is suspected. Postpartum hemorrhage, unless due to the cervical lacerations, usually contraindicates immediate cervical repair unless it has been quickly controlled by oxytocics or uterine tamponade. No obstetric service is complete without a careful pelvic examination at the end of six or eight weeks. At this examination special attention should be directed to the detection of cervical damage. There is little tendency to further healing of the damaged cervix after eight weeks. Lacerations, erosions and endocervicitis are quickly and safely eradicated by electrosurgical methods in the late puerperium, preferably about eight weeks post partum. For the minor lesions the method of linear cauterization with the nasal tip cautery, as advocated by Dickinson, is satisfactory. The author's preference is electrocoagulation with the ball tip electrode or with the Cherry-Ende bipolar electrode. The Hyams conization technic is also suitable in selected cases.

**Herpes Zoster Oticus.**—Hill presents three cases of herpes zoster oticus and states that it is a relatively rare condition. While the exact etiology is still in doubt, it is generally agreed that the causative agent is a filtrable virus. Teague and Goodpasture showed experimentally that the virus can pass along the nerve from some inoculated area to the spinal cord and brain, the transmission being along the axis cylinder of either motor, sensory or sympathetic fibers. The prodromal symptoms may be confined to malaise, headache and slight fever or may be more severe with nausea, vomiting and increasing pain.

Pain is the principal symptom and usually precedes the appearance of the herpetic eruption, although Nattkemper reports a case with typical eruption and facial palsy but no pain. The eruption is vesicular and confined to definite areas, depending on the ganglion involved. Facial palsy is common in the more severe cases. It is now considered that the lesion is not a ganglionitis in any limited sense but an infectious process involving all nerve structures, ascending or descending, and extending to the cortex in some cases. Exposure to cold, excessive heat, exhaustion and shock have been mentioned as predisposing factors. Apparently it is a matter of lowered individual resistance to invasion by the virus. The prognosis is generally favorable, although auditory function may be permanently damaged or lost. Apparently the spiral ganglion is least resistant to the virus and is the slowest to recover. The treatment is symptomatic, directed largely toward efforts for the relief of pain. Any definite focal infection that might have any bearing on a case should be cleared up if possible. During the last few years a number of workers have reported successful results from the use of roentgen therapy. This was used in two of the author's cases with apparent benefit.

**Climate and Upper Respiratory Tract Diseases.**—Montgomery deals with the relationship of climate to diseases of the upper respiratory tract but acknowledges the importance of all other factors. The nose is a factor in maintaining the water balance of the body, and the efficiency of its ciliary and other functions definitely depends on changes in climate. The incidence of head colds, while occurring about the same time of year over the entire continent and Europe, seems to be definitely related to changes in humidity and more especially to marked changes of temperature. A study of natural history suggests that the metabolic condition of all life, both wild and civilized, is affected by climatic changes. Patients suffering from tuberculous disease of the upper respiratory tract appear to do better in certain climates. Climate is a distinct factor in the etiology of diseases of the upper respiratory tract and consequently climate must be considered a factor in its treatment.

**Chronic Infections in Pharynx.**—Schenck summarizes the histologic changes observed in biopsy material from the pharynges of 108 patients with systemic manifestations of disease usually attributed to some form of focal infection. There was no specific alteration in the pharyngeal nodules in one type of disease that would differentiate them from the nodules occurring in another type of disease. Marked hyperplasia with chronic inflammatory change was the rule. Proliferation occurs early, and the increase in the number of polyblasts indicates a stimulation of or attraction for the reticulo-endothelial units. Increase of the number of polyblasts in the central portions of a follicle gives the appearance of a false germinal center. Edema occurs early, but later, when fibrosis is advanced, there is dilatation of the lymph channels due to obstruction and many of the dilated channels contain cellular elements, largely lymphocytes, but also plasma cells and large mononuclear cells. Obliteration of lymph channels seems invariably to result from sufficient proliferation of fibroblasts, but there is also proliferation of endothelial cells within the channels. The perfollicular lymph spaces were obliterated by fibrosis in the abnormal nodules. Hyperplasia of lymph nodules invariably appears to precede proliferation of fibrous tissue in chronic inflammation. The increase of young fibrous tissue elements is followed by a gradual and commensurate disappearance of lymph cells. Prior to the general dissolution of cells, the decrease in the number of lymph cells is coincident with and proportional to the increase in the number of polyblasts. Plasma cells were not numerous in abnormal pharyngeal nodules. Infiltration of the fibrous tissue about the nodules first appeared on that border

of the nodule which faced the epithelium; from this zone both the nodule and the epithelium became invaded. The terminal result of chronic inflammation of the nodule appeared to be a form of hyaline degeneration. No Aschoff nodules were distinguished in the sections from patients with articular pain or choreiform manifestations. If the various systemic effects observed in this series of patients are due to specific microorganisms or to specific viruses, there is certainly no comparable specificity in the coincident alteration of the pharyngeal tissue.

**Clinical Experience with Protamine-Zinc-Insulin.**—Rabinowitch and his associates state that blood sugar time curves obtained in diabetic patients following the administration of a mixture of protamine, insulin and zinc clearly indicated that this mixture was more effective in prolonging the hypoglycemic action of the injected insulin than protamine and insulin only. The results obtained in the human being confirm those of Scott and his co-workers in animals. A number of "insulin wasters" who had previously received treatment with regular insulin and later with protamine insulin were treated with the zinc mixture, and the results obtained show that, though the protamine insulin was more effective than the regular insulin, the control of the diabetes with the zinc mixture was almost perfect. The average insulin requirement in these cases during treatment with the protamine-zinc-insulin mixture was found to be approximately 25 per cent less than during treatment with protamine insulin. The average rate at which it was subsequently possible to reduce the insulin dosage was also found to be greater with the zinc mixture than with the protamine insulin. The addition of zinc to the protamine insulin increased the sensitivity of these patients to the injected insulin. Crystalline insulin was found to have a more prolonged action on the blood sugar than regular insulin, and in some cases its effects were equal to that of protamine insulin. The prolonged action of the crystalline insulin was evidently not due to its purity but to its zinc content. Equally good and in some instances better results were obtained by the addition of zinc to the regular commercial insulin. A number of observations suggest that under certain conditions it may not only be possible to inhibit totally the action of the injected insulin by the use of zinc but also to interfere with the action of endogenous insulin. Aside from the low toxicity of this metal, the possible accumulation of it in the body due to prolonged use of protamine-zinc-insulin is a negligible factor. However, in view of the natural occurrence of zinc in the pancreas in large quantities, it is possible that in zinc may be found the explanation of the resistance to insulin at times encountered in the diabetic state, particularly in infection. Also in zinc may be found the explanation of the transient occurrence of glycosuria occasionally present in infections in general.

**Bromide Intoxication.**—Cross says it is difficult to see how any epileptic patient could have escaped bromide poisoning, in some degree at least, and it is more than probable that many mental symptoms formerly ascribed to epilepsy were really manifestations of a superimposed bromide psychosis. In recent years, many preparations of the barbiturates have been introduced, which have tended to supplant bromides. In spite of this, bromides still have their place, particularly in conditions of nervous tension and anxiety. Their action is quite efficient and they have the added advantage of being inexpensive. Until quite recently little thought was given to the possibility that bromides might do harm to some patients. It was known for years that they produced a skin eruption at times, but this was usually looked on as an annoying and relatively harmless result. Most physicians seem quite surprised to learn that bromides can produce mental symptoms if improperly used. Ordinarily the toxic level is considered to be reached when the blood serum contains 150 mg. per hundred cubic centimeters. Symptoms may appear at lower levels, however, and occasionally are absent at higher concentrations. Bromide is easily demonstrated in the urine. Since the symptoms are predominantly mental, it is usually in psychiatric institutions that the greater number of these cases are detected. Bromide intoxications should be suspected in all toxic psychoses, especially when the onset of confusion and hallucinations has been sudden. It is unwise to wait for a bromide rash, as this is often absent. When administering bromides, it should always be ascertained whether the patient is taking any other form of medicine, the patient's habits regarding the taking of table salt and whether or not the fluid intake is ample. Bromide therapy should be discontinued at intervals, possibly one week out of four. The treatment consists of administering sodium chloride, which drives the bromide out of the tissues and replaces it, thus reversing the reaction occurring during its accumulation in the body. The author's practice has been to limit the use of intravenous saline solution to those who are severely dehydrated and to give the sodium chloride by mouth in all other cases in doses of 30 grains (2 Gm.) three or four times a day. The salt can also be given by rectum, but this is often difficult in a badly excited patient. It is very important to give fluids freely, and the diet should be liquid and of high caloric value.

**Response to Insulin as Index to Dietary Management of Diabetes.**—MacBryde made a study to determine whether diabetic patients who gain tolerance on high carbohydrate can be clinically distinguished from those who do not. The object was to find, if possible, a method for deciding on the optimal type of diet for each individual diabetic patient. Studies were planned to determine whether the two groups differed in their response to high carbohydrate diets. Observations have been made on the response of these patients to high and low carbohydrate diets, and the influence of these diets on the concentration of blood sugar, the glycosuria, the ketonuria, the insulin requirement, the dextrose tolerance and relative insulin sensitivity. The sensitive group of eight patients exhibited a marked fall in the blood sugar, ranging from 61 to 75 per cent of the fasting levels. All reached a blood sugar level of 68 or less, the average of the lowest determinations being 52 mg. per hundred cubic centimeters. Definite signs of hypoglycemia were observed in every patient of this group, and two experienced quite severe reactions. The relatively resistant patients showed much less response. The fall ranged from 32 to 53 per cent; none reached a point below 71 mg. per hundred cubic centimeters, and the average of the lowest determinations was 90 mg. Signs of hypoglycemia were minimal or absent. Intravenous insulin tolerance tests on three of the patients in each group indicated that possible differences in absorption of the subcutaneous insulin could not explain the observed differences in response. In each instance a patient sensitive to subcutaneous insulin was found also to be sensitive to intravenous insulin. Those relatively resistant showed relatively poor response to both the subcutaneous and the intravenous injections. The tolerated overdose in those patients found to be sensitive in the insulin tolerance tests was in every case practically zero. An increase of as much as 3 or 5 units produced hypoglycemia, while a reduction of 3 or 5 units below the required amount led promptly to glycosuria and hyperglycemia. In the resistant group, however, increase in the insulin dosage had a relatively slight effect. The dextrose equivalents, representing the number of grams of dextrose metabolized per unit of insulin, was found to be higher in the insulin-sensitive group. On the average, there appears to be approximately four times as much effect per unit in the sensitive group as in the resistant group. Those patients showing relative resistance are usually older, frequently are obese and often have vascular hypertension. There is little tendency to acidosis, while the sensitive group develop acidosis and coma much more easily. The sensitive group are usually younger, are often thin and have as a rule low blood pressures.

It is doubtful, however, whether clinical features alone will serve to distinguish the two types. They cannot be distinguished as to severity, since the insulin requirement is on the average higher in the resistant group; but acidosis occurs more frequently in the sensitive type. The relatively resistant group without exception gained tolerance on a high carbohydrate intake. In several instances this was shown to be accompanied by increased sensitivity to insulin. The insulin-sensitive patients resemble in many respects the partially pancreatectomized animal. They respond well to exogenous insulin but seem to produce too little of the endogenous hormone. When subjected to the excessive burden of a high carbohydrate intake they may lose tolerance, perhaps as the result of overburdening the damaged or numerically decreased pancreatic islets. Relatively resistant patients, however, react as if the endogenous insulin supply were adequate in amount but operating under the handicap of inhibiting factors.

Contact Dermatitis Caused by Jonquil (*Narcissus Jonquilla*). G. V. Stryker, St. Louis.—p. 462.

**Poisoning by Vapors of Beryllium Oxyfluoride.**—Gelman states that the first phase of the clinical course of this industrial poisoning consists of a feverish state following the work in the foundry, which is like metal-fume fever. The second phase usually develops gradually two, three, four or more days afterward and can be characterized as an extensive bronchiolo-alveolitis, with a tendency to relapses and exacerbations. Its symptoms are severe dyspnea, cyanosis, paroxysmal coughing and high temperature. Pneumonic complications are rare. Edema of the lungs has not been observed.

**Contact Dermatitis Caused by Jonquil (*Narcissus Jonquilla*).**—The narcissus, which belongs to the natural order Amaryllidaceae, has more than 100 subvarieties. Among these the most widely grown are the daffodil (*Narcissus pseudonarcissus*) and the jonquil (*Narcissus jonquilla*). An operator of a large greenhouse in St. Louis County consulted Stryker because of a severe eruption of his hands. An acute, vesicular dermatitis appeared on the sides and backs of both hands in February 1935 and continued until April 1935. His hands were well until October of the same year, when a second and more severe attack occurred. At the time of examination, December 1935, the backs of the hands were covered with an acute, scaly, red, vesicular dermatitis. The patient volunteered the information that, though he was sensitive to chrysanthemum, he felt that his condition was due to jonquils, as he was working with them when the attacks occurred. Patch tests were done with all substances with which the patient was known to come in contact. Chrysanthemum produced an erythema, jonquil sap an erythema and vesiculation, jonquil stalk an erythema and vesiculation, and jonquil petal an erythema. All other substances tested gave a negative result. Improvement and complete cure followed the removal of the contact. A recurrence was experienced following a short exposure while visiting a greenhouse in another city. Following this experience the patient has remained well and he continues to avoid contact with the narcissus. Investigation of the greenhouse in question revealed that out of a total of fifty employees about 20 per cent were known to be affected by handling narcissus. Examination of five volunteers showed that they had a dermatitis of the hands and arms. The eruption varied from a few small patches to an involvement of the exposed parts. The time of employment was four, seven, twelve, fifteen and twenty years, respectively.

**Blood Sedimentation Rates in Old Persons.**—To ascertain whether the sedimentation rate would be a simple method of diagnostic value in the examination of the aged, Miller made 621 sedimentation rates on 496 apparently normal old men during the routine admission examinations to the New York City Farm Colony. The study concerns itself with men more than 50 years of age. Degenerative diseases are in the ascendancy in this group, and the sedimentation rate is not affected by degenerative changes, as 66 per cent of the patients had rates under 10 per cent, and 86 per cent had rates under 20 per cent. Age has little effect on the sedimentation rate. The slight variations present are due to the different number of cases in the various age groups. The daily wear and tear of body tissue cause only slight changes in the rate, and it remains within normal limits. Tissue destruction, whether inflammatory or neoplastic in origin, causes an increase in the sedimentation rate. The test is not diagnostic of any disease, but an increased rate in an apparently normal person should be viewed with suspicion and call for further investigation. Malignant manifestations, when localized, do not cause an increased sedimentation rate; only when necrosis, secondary infection and metastases occur are the rates increased. A single normal sedimentation rate does not rule out a malignant condition. Of twenty-nine cases of diabetes, 52 per cent showed an increase in the sedimentation rate. The author's tuberculous patients are mainly old fibrotic cases with negative sputums, and their sedimentation rates vary from normal to very high. One patient with a rate of 28 per cent advanced within six months to 45 per cent, at which time the sputum was Gaffky VI and a roentgenogram showed an advancement of the lesion. The patients with syphilis, like those with tuberculosis, had rates varying from normal to very high. The tabetic patients had normal rates, while those with central nervous system and cardiovascular involvement had increased rates.

**Cysts of Prostate Gland.**—Emmett and Braasch divide cysts of the prostate gland into congenital and acquired. Cysts of any significance are the congenital cysts, retention cysts and cysts that occur in connection with carcinoma of the prostate gland. Congenital cysts are rather uncommon, and one often is at a loss to explain the mechanism of their formation. The simple retention cyst may arise in any portion of the prostate gland and is nothing more than a normal prostatic acinus lined with simple columnar epithelium, the outlet of which for some reason has become occluded, forcing the acinus to expand. Because of the dilatation, the epithelium becomes thinned, so that the microscopic examination reveals that the inner wall is lined with flattened columnar epithelium. If the cyst is situated near the surface of the prostate gland and projects into the urethral lumen or bladder, the outside of the cyst will be covered with the corresponding mucous membrane of the urethra or bladder. One side of the cyst is practically always well embedded in prostatic tissue. This is not the only mechanism in the production of a cyst. The authors have seen many sections in which the walls of neighboring dilated acini were breaking and rupturing into one another and producing one large dilated acinus or small cyst. It is difficult to distinguish a large dilated prostatic acinus from a small cyst. Because of the frequent occurrence of these smaller prostatic cysts, the authors have chosen to report only the fourteen cases in which

the cyst measured 0.75 cm. or more in diameter. Seven of these cysts were found accidentally at necropsy. Six of these had produced no symptoms, while one was associated with a marked hypertrophy of the median lobe of the prostate gland, which was producing symptoms of urinary obstruction. Three of the cysts were found in prostate glands that were removed suprapubically because of prostatic hypertrophy and urinary obstruction, while the remaining four cysts were diagnosed clinically. Thirteen of these fourteen cysts were of the simple retention type, while one was thought to be a congenital cyst, probably produced by nonobliteration of the müllerian ducts or wolffian bodies. The symptoms produced by a cyst of the prostate are purely expressions of the mechanical difficulties involved. With the modern cystoscopic equipment the diagnosis of a prostatic cyst that projects into the prostatic urethra or bladder is not difficult. Most of the prostatic cysts that have been discovered in the course of cystoscopy can be treated by fulguration or transurethral resection. The smaller retention cysts that are palpated in the course of rectal examination and that do not produce any symptoms are probably best left alone. Aspiration has been advocated, but the usual result is simply a refilling of the cyst. Large cysts in inaccessible situations may necessitate a suprapubic or perineal operation. There is no doubt that retention cysts of the prostate sometimes do rupture and disappear spontaneously.

**Arachnidism.**—Hargis has devised a routine treatment for spider bite cases. One-fourth grain (0.016 Gm.) of morphine sulfate is given, repeated, if necessary. Calcium gluconate, 10 cc. of a 10 per cent solution, is given intramuscularly and frequently repeated if necessary. Dextrose, 50 cc. of a 50 per cent solution, is given intravenously and also repeated if necessary. The patient is immersed in a hot tub for an hour or more, once or more often if necessary. Then he is put to bed, covered well and kept warm, preferably with a radiant light. Fluids are forced and constipation and urinary retention are avoided. Of the forty-three cases of arachnidism that have been admitted to the hospital in the last fifteen years there have been no fatalities.

**Artificial Fever Therapy of Syphilis and Gonococcal Infections.**—Simpson has given artificial fever treatments to 193 patients, under observation for from six months to four and one-half years, on account of syphilis or gonococcal infection. There were thirty-one patients who received treatment for primary and early secondary syphilis and eighty-nine for neurosyphilis, ocular syphilis or resistant seropositive syphilis. Forty-five patients were treated for gonococcal arthritis, and twenty-eight patients received treatment for gonococcal infection other than gonococcal arthritis. With two exceptions, all persons with syphilis were treated as ambulatory patients. Patients with gonococcal infections have been admitted to the hospital for a period of two weeks. This plan permits close supervision of the patient and eliminates the uncooperative patient. Artificial fever therapy by physical means should be restricted to institutions in which the physician and nurse personnel have received adequate preliminary training. In the hands of skilled and devoted workers this form of therapy seems destined to occupy an increasingly important place in therapeutics. The frequent observation that the best results occurred when neurosyphilis was treated with combined fever and chemotherapy during its earliest manifestations led the author to apply the treatment to patients with primary or early secondary syphilis. The results provide evidence that fever therapy may be of great value in early syphilis, particularly when chemotherapy alone appears to be inadequate. The results obtained in the treatment of symptomatic neurosyphilis, asymptomatic neurosyphilis, ocular syphilis and resistant seropositive syphilis are at least comparable, if not superior, to the results obtained with the more hazardous, time consuming and inconstant malaria therapy. There is evidence that artificial fever therapy fortifies and intensifies the action of antisyphilitic chemotherapeutic agents. High, sustained, controlled artificial fever is the treatment of choice for gonococcal arthritis. Gonococcal arthritis is a manifestation of a systemic disease, requiring systemic treatment. In vitro thermal death time studies and the clinical response of patients with gonococcal infections to artificial fever therapy indicate that it is possible in most instances to destroy gonococci in the various lesions of the disease with high, sustained body temperature. In addition to this sterilizing effect, there is evidence that artificial fever therapy stimulates immune reactions. In twenty-eight patients with gonococcal infection, other than gonococcal arthritis, all evidence of gonococcal urethritis and its complications had disappeared in twenty-five

(89 per cent) at the conclusion of the course of fever therapy. The remaining three patients received apparently inadequate fever therapy.

**Study of Hypogonadism and Cryptorchidism.**—In a review of the records of 521 boys with endocrine or non-endocrine conditions, Gordon found that hypogonadism and cryptorchidism occur almost twice as frequently in the endocrine as in the nonendocrine group. Studies on thirty-eight boys with cryptorchidism and thirty-six with hypogonadism with descended testes show on the average a thyropituitary deficiency as manifested by low basal metabolic rate, low specific dynamic action of proteins and high blood values of cholesterol, chlorides and uric acid. The treatment of cryptorchidism in this series is based on the assumption that it is a symptom in the majority of instances of a disturbed thyropituitary-gonad relationship and not a clinical entity. Three methods are used: (1) oral administration of thyroid and anterior pituitary extracts in increasing dosage, (2) oral administration of thyroid and anterior pituitary extracts and hypodermic injection of anterior pituitary extract and (3) oral administration of thyroid and anterior pituitary extracts and hypodermic injection of anterior pituitary-like extract. Complete descent of the testes was obtained with the three methods as follows: first, 33 per cent; second, 50 per cent; third, 57 per cent. The treatment of cryptorchidism by any of the methods used may be effectual at any age between 2 and 14 years but is more effective after 5 years. No boy should be subjected to an operation for undescended testicles until he has been given the benefit of organotherapy for at least six months. Hypogonadism, especially when associated with adiposogenital dystrophy and hypothyroidism, responds in the majority of instances to oral administration of thyroid and anterior pituitary extracts and hypodermic injections of anterior pituitary extract. Extract of pregnant urine is necessary only in the stubborn and protracted cases. Improvement in the basal metabolic rate, specific dynamic action, general endocrine condition and obesity is generally but not always accompanied by the same degree of improvement in the hypogonadism and cryptorchidism. The effects on the phallus, serotum and testes are not parallel. Untoward effects may result from the use of either anterior pituitary or anterior pituitary-like extracts.

 \*Allergy as Cause of Frequent Colds and Chronic Coughs in Children. N. W. Klein, Seattle.—p. 347.

**Treatment of Empyema of Children.**—Bilderback and Goodnight have treated thirty-two consecutive cases of empyema with a mortality of 6.2 per cent. There were twenty-one cases of metapneumonic empyema and eleven synpneumonic. Twenty-three have been treated by aspiration alone. The average number of aspirations per patient has been twelve. The average number of thoracenteses necessary for the patient to become and stay afebrile was eight. The average number of days for the patient to become and stay afebrile was twenty. The average number of days in the hospital after the last thoracentesis was sixteen. The average hospital stay was forty-two days from the time diagnosis was made. Nine patients have had closed drainage. The average number of aspirations before surgery was five. The average number of days after the diagnosis was made before surgery was twelve. Twenty-one of the thirty-two cases have been admitted in the last four months. Nineteen of these have been treated with repeated aspirations, or 90.4 per cent, in comparison with 42.5 per cent for the first six months. The authors perform thoracentesis with the patient in the sitting position. A little codeine given before aspiration often helps in keeping the child quiet. Infiltration with 1 per cent solution of procaine hydrochloride is then done. A fine 26-gage needle is used for infiltrating the deeper structures including the pleura. When the pleura is penetrated there is a definite "give" to the needle. Aspiration is then done to make sure the needle is in the empyemic cavity. A 13 gage needle with a side opening connected with a rubber tube clamped

with a hemostat is then introduced. A 50 cc. syringe is connected to the tube, the hemostat opened and 50 cc. of pus withdrawn. This is replaced with 40 cc. of air. The process is repeated until air is obtained in the syringe. The cavity is then irrigated with 1:3,300 azochloramide solution until the return is clear. As long as the patient is febrile and there is fluid present on physical examination or fluoroscopy, aspiration should be done daily until he is afebrile. Thoracenteses are then done as necessary according to the child's condition (fever, pulse, appetite and general condition) or according to the fluoroscopic observations. The authors cannot agree with Danna that it is necessary to empty the cavity completely. Although it may be necessary to remove fluid for a short time after the patient is afebrile, suddenly the fluid will not reaccumulate and the little remaining fluid will rapidly absorb. This has been true in practically every case. In replacing the fluid with air the patient is made more comfortable without any danger of a large mediastinal shift. It undoubtedly helps to prevent adhesions. There is less damage to the pleura and there is less danger of puncturing the lung. More complete emptying of the cavity is possible, as the pleura does not come in contact with the needle. Immobilization and rest of the diseased lung is brought about, which aids in healing the focus of infection, without which healing will not take place no matter what the treatment. The air is slowly absorbed, restoring the negative pressure. When the air is absorbed, the cavity is obliterated. Aspiration plays an important part in the surgical treatment of empyema. Diagnostic puncture should always be made to learn the type of fluid and organisms. Aspiration is the method of choice to relieve pressure and toxemia without shock and to get patients in good condition for surgery. A small percentage of the patients are cured before surgery.

**Allergy as Cause of Colds and Coughs.**—Clein warns that the children presenting the symptoms of frequent colds and chronic coughs have usually visited many physicians. Nevertheless, the true condition is probably overlooked more often than any other common present day disease. These patients have received many types of treatment in an effort to relieve the persistent symptoms. Their history usually states that they have had tonsil and adenoid removal one or more times, "cold shots," vitamin D products, light treatments, sinus treatments or have been sent to a warmer climate for the winter, all with no relief. In fact, they are usually worse. This history should immediately put the physician on his guard to make him think in terms of allergy. In the diagnosis of acute and chronic rhinitis, croup, paranasal sinusitis, laryngitis, tracheitis and bronchitis the possibility of allergy must be considered. In children, acute and chronic infections may obscure a primary underlying allergic condition. The most constant symptom of nasal allergy is a "stuffy nose which is always worse on arising in the morning." A chronic cough, occurring especially during the early morning hours, is a preasthmatic symptom. Treatment on the basis of climination and specific desensitization of pollens, epidermals and dust gives excellent results in children.

**Causes for Failure in Treatment of Diabetes.**—Finley divides the treatment of diabetes into three parts. 1. To clear up or prevent the immediate symptoms of dextrose deprivation,

such as glycosuria, dehydration, malnutrition and the profound cellular chemical changes antecedent to and productive of severe acidosis and coma. 2. To guard the patient against considering his diabetes a threat against his self esteem. 3. To help the patient evolve a plan or pattern of dietary and therefore of social and work conduct, which he is willing to follow and which gives most promise of avoiding the development or the advance of arteriosclerosis. These three objects run concurrently and are best begun at the first conference with the patient. Undernutrition must be avoided and a hyperglycemia alone or a glycosuria alone cannot be accepted as a trustworthy evidence of the condition. Attempts to keep a patient on a diet too low in nutritional value in order to clear the urine of sugar when the blood sugar is within acceptable limits, to keep a blood sugar at some conventionally accepted normal level when the kidneys are not leaking sugar or to avoid the use of insulin cannot be accepted as the best medical practice, because it may be using a state of undernutrition as the means to treat a chemical change. Persistent glucosuria, when present with persistent hyperglycemia, is bound to lead sooner or later to undernutrition and must be cleared if possible. Glycosuria in the absence of a chronic focus of infection is due to a delayed absorptive activity of the tubules of the kidney, which returns the sugar from the glomerular urine to the blood. The logical treatment seems to be to allow a diet which yields enough dextrose to supply both that lost in the urine and that needed to maintain a normal state of nutrition, and then to follow the blood sugar more frequently than would be called for otherwise in order to be sure that the glycosuria and a hyperglycemia are not occurring together.

\*Certain Factors Supposed to Influence Results of Treatment of Leprosy. J. G. Tolentino, Mandawe, Cebu.—p. 163.

**Treatment of Leprosy.**—Tolentino reviewed the records of 477 patients admitted to the Eversley Childs Treatment Station from 1929 to 1933 inclusive. These patients were treated almost entirely with Hydnocarpus wightiana oil or its ethyl esters either iodized or cresotated. The severity of skin lesions was found inversely proportional to the percentage of paroled patients. The duration of the disease was found to have apparently no relation to the results of treatment. The age on admission was found to have a definite relation to the results of the treatment in that the first, fourth, fifth and sixth decades gave higher percentages of paroled patients than the other decades. The results, if plotted with age, gave a curve that goes down from the first to the third as the lowest point, gradually rising to the fifth decade as the highest point, from which it goes down again. The results of the treatment were

found to be apparently better among women than among the men, except in the fifth decade, probably owing to the menopause, which disturbs the physiologic life of women. Puberty and childbirth did not seem to be important factors in the treatment among these cases. The degree of nutrition was found to have a definite relation to the results of treatment. The results are inversely proportional to the degree of obesity of the patients. It appears that excess fat in the body has an unfavorable effect on the treatment of leprosy.

**Vaccine Treatment of Chronic Arthritis.**—Greer searches for focal infections and prepares the vaccines in the usual manner. A period of vaccine treatment is first instituted before an attempt is made to deal with the focal area. In this way the grave danger of precipitating extensive lesions, which at times quickly follow the removal of infective foci, may be obviated. The first intravenous inoculation consists of 100 micro-organisms. Usually, after the inoculation the patients notice decidedly favorable responses consisting of a lessening of their joint symptoms, muscular relaxation and a sense of euphoria. This response may appear from thirty minutes to four hours after the injection and may persist for as long as forty-eight hours. If the patient's condition remains entirely stationary following the inoculation, the next dose is increased to 200 micro-organisms and continued in this manner until a favorable response is obtained. Only when the dose, which previously gave a favorable response, fails in that direction, is the quantity increased. If a reaction is elicited, the dosage is considerably reduced and a favorable response again sought for. The interval of time between inoculations is gaged entirely

by the duration and the character of the favorable responses following their administration. If these two factors are prominent, the subsequent injection is made when the patient's symptoms begin to level off into a stationary period. Ordinarily this interval is approximately forty-eight hours. There were thirty-two women and eighteen men treated. Their average age was 40.8 years. The duration of onset of the disease varied from one week to ten years. Only one joint was involved in fifteen patients, two joints in six, three joints in four, and five joints in twenty-four. Foci of infection were found in thirty-nine patients, and in only eleven of this number was it possible to eradicate completely the apparent focus by surgery. These were all afflicted with either diseased tonsils or teeth. The others were treated palliatively. The period of time during which these patients were treated varied from one month to three years; the average period was 10.5 months. Improvement was obtained in forty-four patients (88 per cent). The benefit in four of these was moderate in degree. The remainder (80 per cent) were greatly helped. Twenty-nine patients apparently recovered. Three of this number suffered a recurrence of arthritis, leaving twenty-six patients (50.4 per cent) who had no recurrences. The average period was more than eighteen months since the discharge of the latter patients and more than twenty-two months in all but seven. The remaining nineteen patients, classified as cured, were completely well after a period of twenty-four months. Therefore at least 73 per cent of the recovered patients may be estimated as having been cured, since an average time of two years had passed since they were pronounced well. Of a control group of fifty-three cases of chronic atrophic arthritis which were treated immediately preceding the institution of the intravenous vaccine treatment, 55.5 per cent showed improvement, as contrasted with the 80 per cent. This considerable difference bespeaks the greater advantage of the intravenous method in the treatment of chronic rheumatoid arthritis. Stainsby's poor results with the subcutaneous method accentuate this belief.

### West Virginia Medical Journal, Charleston

32: 441-488 (Oct.) 1936

Forty Years of Obstetrics. C. H. Maxwell, Morgantown.—p. 467.  
Caesarean Section: Summarizing of 197 Cases. J. R. Bloss, Huntington.—p. 470.

**Electrotherapy in Endocervicitis.**—Dearman has used the Cherry electrocoagulation treatment on 269 cases. Only twice was it necessary to repeat the treatment for complete healing of the endocervicitis. Cauterization was used on seventy-one patients requiring a repeated treatment thirty-three times, making a total of 104 cauterizations. All coagulation treatments were given within the last two and one-half years. Seven have since become pregnant. Two have been delivered with no evidence of dystocia. One case of unrecognized pregnancy was undisturbed. Should an acute condition of the pelvis develop following cauterization or electrocoagulation, it should be treated as any acute pelvic condition, such as follow abortions or deliveries. The author's preference would be the Elliott treatment, with no rush to open the abdomen and, if abscess formed, drainage if possible by posterior vaginal section or Cullen's method. There is one variation in his later care of the patients from other reports he has studied. He instructs them to wash frequently but not to take douches. He makes no effort to remove the coagulum but dilates the canal with a small applicator with tincture of iodine. Before the first treatment he cleanses the cervix with an antiseptic and uses 15 per cent cocaine. Treatment is somewhat painful, but the pain lasts only about half a minute. Ideal results with the cautery require greater skill than with the Cherry treatment. Stenosis is due to overcauterization into muscle, and recurring endocervicitis is due to undercauterization that does not reach the diseased glandular tissues. Treatment of the cervical canal to within one-eighth inch of the internals is necessary for cure. This is more difficult when accomplished with the cautery. In the Cherry cases there were two cases of mild cervical stenosis that were relieved easily by one dilation at the office.

Abnormal Dick Reaction. E. W. Goodall.—p. 207.

**Blood Studies in Infancy.**—Stewart reviews the more important blood studies in infancy and reports a series of blood counts and hemoglobin estimations on full-term and premature infants. For comparison a number of figures taken from the literature are quoted. The hemoglobin percentage and red cell counts of sixty-one infants have been recorded at weekly intervals between the ages of 2 days and 27 weeks. There is a rapid reduction in the hemoglobin immediately after birth, the maximal drop occurring between the ninth and the eleventh week. The red cells also fall, but the color index remains high and is often greater than 1.0. After the third month there is a gradual rise in hemoglobin and red cells until the sixth month. Full-term children reach a higher hemoglobin level than twins or premature children (84 and 70 per cent respectively), but the average counts show little difference in the two series (3.97 and 3.92 millions respectively). The hemoglobin values in the present full-term series are higher than the corresponding ones obtained by Mackay for breast-fed children and approximate to her ideal "normal" standards. Those for the premature infants and twins are also higher than Mackay's series for infants of low birth weight but correspond closely with the observations of Josephs in premature infants. It is rare for the color index to be low before the seventh month, the average value at this age being 0.92. In older children who develop anemia the color index is usually low, the number of red cells often remaining normal in spite of the hemoglobin falling to 50 per cent.

**Transplantation of Cornea.**—Thomas has done thirty-six consecutive operations for corneal transplantation, of which twenty-four were performed on twenty-one suitable eyes. About 80 per cent of the patients were benefited by the operation, 28 per cent were clear with vision of 6/36 or better, 70 per cent of the operations were successful, and 25 per cent resulted in clear grafts. The author quotes the results of Elschnig, Filatov and Castroviejo from which it is seen that the operation of corneal transplantation is one that should be included in the list of operative procedures which can be legitimately employed in suitable cases. The study of the operation is yet far from completed. Attention to detail is an essential requirement, and minute experimental departures from routine should be tried singly and not collectively, so that a logical inference may be drawn from the result. The outlook in the future for patients more or less blind with corneal opacities is decidedly

encouraging, and in suitable cases there is even now a 70 per cent chance of improvement and a 25 per cent chance of obtaining good useful vision. The future will hold some chance of improvement for many of the cases that are, for various reasons, classified as unfavorable.

**Complement Fixation Test in Diagnosis of Weil's Disease.**—Pot and Dornickx applied the complement fixation reaction in the diagnosis of Weil's disease. In the preparation of the antigen cultures of leptospira approximately one week old in Korthof's medium are centrifuged at 3,000 revolutions per minute or more for three or four hours. The supernatant fluid is pipetted off and the deposit is resuspended in 0.3 per cent phenol-saline solution. The quantity must be 1:10 of the original quantity of the fluid medium. The antigen is a turbid fluid, which shows only remains of leptospira after it has been in the ice chest for a few days. For the titration of the antigen a series of antigen dilutions in phenol-saline solution is mixed with a hundredfold dilution of an inactivated highly positive serum and a tenfold dilution of fresh guinea-pig serum (complement), 0.3 cc. of each. After thorough shaking the tubes are incubated at 37 C. for one hour. After this, 0.6 cc. of the hemolytic system is added. The rack is incubated for thirty minutes, after which the reading is taken. If the antigen has been sufficiently active, hemolysis is completely inhibited in the first tubes, which contain the largest quantities of antigen. In the remaining tubes the inhibition is incomplete or absent. The last tube with complete inhibition indicates the titer. In the test proper, in accordance with Gaetgens, the authors carry out the test quantitatively; i. e., they determine the dilution of a positive serum which just gives complete inhibition. The reaction is not more intricate in its execution than the Wassermann test. There were 100 serums sent in for examination for Weil's disease in which the results of the agglutination and lysis tests could be compared with those of complement fixation. There were seventy-three serums in which both reactions were negative, nineteen in which both reactions were positive, one in which both reactions were doubtful and seven serums in which the complement fixation test was negative and agglutination and lysis tests were slightly positive.

 \*Intravenous or Intraperitoneal Antitoxin Treatment, Combined with Short Isolation Period, in Scarlet Fever. H. S. Banks.—p. 559.

**Impaired Dextrose Tolerance in Alimentary Disorders of Childhood.**—Ross has found the dextrose tolerance curves to be high in the fifteen cases so far examined, even though some of these did not show gross flattening of the oral curve. In ten cases of chronic intestinal indigestion investigated, he has found a normal fecal fat output associated with a flat oral dextrose tolerance curve and a high intravenous one. He has investigated three cases of abdominal tuberculosis which have shown flat oral and high intravenous curves. The administration of liquid liver extract (half an ounce [15 cc.] twice daily), either enterally or parenterally, has been shown to improve the dextrose tolerance when it is impaired in these conditions.

**Intravenous or Intraperitoneal Antitoxin Treatment.**—This study deals with a series of 1,877 cases treated with intravenous serum and controlled with a nonserum treated series of 1,419 cases, mostly in separate wards, during the years 1933 and 1934. Banks found that a single dose of from 10 to 20 cc. of scarlatinal antitoxin injected intravenously or intraperitoneally within the first three days of onset considerably modifies the course of both simple and septic scarlet fever. By this means the average hospital isolation period has been reduced successfully to about two weeks for adults and three weeks or less for children. The application of this routine in all definite cases of scarlet fever admitted to hospital wards in the acute stage has been associated with a substantial and significant reduction of morbidity. Thus, otitis media has been reduced to one third and nephritis to less than one seventh of the incidence in untreated controls. The intraperitoneal route of injection of antitoxin in this disease has yielded results almost identical with those of the intravenous. Since the technic of intraperitoneal injection at all ages is simple, and danger from shock is negligible, with adequate aseptic safeguards the method is susceptible of wide practical application.

 \*Tropical Macrocytic Anemia. L. E. Napier.—p. 679.

**Method of Spacing Irradiation in Treatment of Tumors.**—Mottram and Morton state that the method of spacing irradiations is based on two facts. The first is that cells under anaerobiosis are more resistant to irradiation than well oxygenated cells. The second is that radiation, through action on capillaries and small blood vessels, interferes with the circulation of the tissue or tumors irradiated, so much so that when an animal bearing two tumors, one irradiated and that when an animal bearing two tumors, one irradiated and one nonirradiated, is inoculated with India ink a few days after the application of radiation, it is found that the ink enters the normal tumor but fails to gain entrance into the irradiated tumor. It follows that, during the interference with the circu-

lation following irradiation, tumors must be radioresistant and that they will not again become radiosensitive until this damage to the blood vessels has been recovered from. Thence the system of spacing irradiation which took account of these factors might in certain cases prove both practicable and justifiable in the treatment of patients suffering from malignant disease. Treatment is administered either continuously or at short intervals until the tumor shows an initial decrease in size; it is then discontinued until the measurements show an increase, when the process is repeated. Side by side with the treatment of patients, a set of tar warts in mice has been treated by spaced gamma irradiation. These likewise showed regression following treatment within a day or two and without any latent period. More especially is this the case once the growth of the tumor has been controlled, when small doses of radiation suffice to produce much regression. On the whole it appears that these diminutions in size are not due to destruction and disappearance of tumor cells but rather to fluctuations in the blood supply to the tumors, which form waves on the slower regression, owing to disappearance of tumor cells. By applying treatment only during periods of growth and withholding it during periods of regression, tar warts have been cured in mice and tumors in man have been benefited with no more than trivial damage to the surrounding normal tissues, such as transient erythema or partial epilation.

**Tropical Macrocytic Anemia.**—Among the cases of anemia admitted to the Hospital for Tropical Diseases in Calcutta during the last year, Napier observed eleven cases of macrocytic anemia that responded to treatment with an autolyzed yeast preparation; four of these patients were nonpregnant women and seven were men. The hematologic observations in these cases are similar to the changes in Wills' tropical macrocytic anemia, except that the indirect van den Bergh reaction was positive in nine, and there was other evidence of increased blood destruction. It seems that, in addition to the vitamin B complex deficiency, there must be other causes of this condition. It is suggested that excess hemolysis of red blood cells may be an associated factor in this macrocytic anemia.

 Radiologic Treatment of Cancer of Tongue. L. J. Clendinnen.—p. 228.

**Radium Treatment of Cancer of Tongue.**—McDowall has been treating cancer of the tongue since 1928 with the interstitial application of radium. Although his figures are small, he finds on comparing them with those of other workers who have larger numbers to deal with that there is not a great deal of difference in the average results. Of his patients treated in 1929, approximately 33 per cent are now alive and apparently cured. The greater number of the 33 per cent of cured patients come from what he considers to be the favorable group, that is, those with no palpable glandular involvement at the beginning of treatment. Of the patients in whom there were palpable glands at the time of treatment, only two now survive, and he is of the opinion that the result in these two cases was due more to other causes than to the method of treatment. In most of the patients with glandular involvement who received radiation treatment there was some improvement. This amounted in a few instances to a temporary disappearance of the glands and in others to a shrinkage or regression of the glands. In the majority even of the unfavorable cases there has been at first considerable diminution of pain. Subsequent treatments to the glandular growths were never so effective as the first. In the majority of cases in which there was secondary glandular involvement the period of survival ranged from a few weeks to eighteen months, although the average survival time was from seven to eight months.

**Rodent Ulcer.**—In more than 600 private cases of rodent ulcer, Newland has found five examples of rodent ulcer of the upper extremity. The growths had been present for from ten to thirteen years. The situation of the growth on the limb was on the back of the wrist, the antero-external aspect of the elbow, and the middle of the radial border of the forearm in the men, and the front of the elbow and the middle of the flexor aspect of the forearm in the women. Associated with the rodent ulcers were other growths in every instance but one. All the growths were situated on regions of the upper extremity subject to exposure to the weather, and the skin of all the patients showed evidence of this. Two of the men cited injuries to explain the development of the growth. The author treats early rodent ulcers in the following way unless the growth has attacked the bone, cartilage or conjunctiva: A local anesthetic of procaine hydrochloride is injected around the growth. When the part is anesthetized, the growth is curetted with a stainless steel curet. A rodent ulcer yields to a curet just like granulation tissue, and a smooth surface is left. After a thorough curetting, only a thin layer of the rodent ulcer cells is likely to remain. These are still further reduced by searing the raw surface with an electric cautery. This has the advantage of leaving a dry surface as well as destroying cancer cells. One or two radium 10 mg. plaques are now applied without a filter to the curetted surface and to the edges for an hour. The process is repeated, a thin filter being used. Except in the case of insignificant growths, an erythema dose of x-rays is given as well. With this treatment very few recurrences have occurred and the cosmetic results have been excellent.

**Industrial Diseases of Lungs.**—Cooke in his discussion of the industrial diseases of the lungs states that of all the dusts generated during mining, quarrying and manufacturing processes only two (silica and asbestos) have been proved to be biologically active and to cause extensive disease in workers. To produce silicosis there must be an admixture of silica. The incidence of the disease is extremely small and falls solely on those engaged in drilling and handling sandstone. About 60 per cent of the dust particles are trapped by the physiologic defense of the respiratory tract before reaching the larynx. The protective mechanism is very efficient unless constantly overwhelmed over a long period by the presence of particles of dust in the air less than 10 microns in length. Workers exposed for years to atmospheres containing not more than from 10 to 20 million particles per cubic foot escape, whereas in those breathing higher concentrations silicosis eventually develops. The length of time required for silicosis and asbestosis to develop and death to ensue may be gathered from the report of the chief medical inspector of factories, in which the average duration of employment varied from 6.4 to 39.2 years. To produce a reaction either in subcutaneous tissue or in the lungs a dust must be soluble. Silica is soluble to the extent of 1 in 10,000 parts of distilled water, and the solubility is increased by the presence of alkalis, and increased too as the size of the particle diminishes. At least 75 per cent of patients with silicosis contract tuberculosis. The silicotic lung is susceptible to infection and this susceptibility increases with the amount of damage produced by silica. Other infections are not uncommon. Influenza, bronchitis and pneumonia account for 6 per cent of the deaths of those certified as silicosis in South Africa. The earliest roentgen manifestation is an increase in the density of the shadows of the vascular tree. The earliest indications are in the middle and lower zones of the lung. Increase in the root shadow due to involvement of the glands is constant.

\*Interrelation of Antigenic Properties of Snake Venoms and Its Bearing on Polyvalence and the Assay of Serums. E. Grasset.—p. 367.

**Antigenic Properties of Snake Venoms.**—Grasset believes that the standardization of venom antibodies generally, and in this particular instance of the viperidae and colubridae antibodies of polyvalent serum should be effected by a preliminary comparison with a specific standard serum for each of the two groups. Such serums, the neutralizing potency of which is exactly determined, would, after being dried, enable a defined specific antivenom unit to be adopted. By determining test doses of the corresponding venoms in relation to the antivenom unit adopted for these specific serums and carrying out subsidiary assays of the polyvalent serum in relation to these test doses, it will be possible to measure the antibody content of this serum in terms of anticobra and anti-Bitis units. The assay of antivenom serums in relation to standard serums would have theoretical and practical advantages over a method of direct neutralization tests against increasing quantities of venom (mg.) or methods involving the use of numerous lethal doses of venom, for the toxicity of the latter is liable to vary greatly under the influence of individual and seasonal factors, the effects of life in captivity and diet. The international standardization of antivenom serums on a principle similar to that adopted for the standardization of bacterial antitoxins would have the advantage of providing a satisfactory standard of reference for the assessment of the specific, relative and therapeutic neutralizing potency of antivenom serums, at all events within such limits as the specificity of venom antigens allows.

\*Barium Enema Controlled by Roentgen Rays: First Use in Diagnosis of Localization and Treatment of Acute Intestinal Invagination of Nursling. D. Ferey.—p. 607.

**Barium Sulfate Enema in Treatment of Intestinal Invagination.**—Ferey discusses the use of the barium sulfate enema in the localization and treatment of acute intestinal invagination in nurslings. The barium is retained simply by pinching the infant's anus between the thumbs. Its use for this purpose should be employed only in the presence of a surgeon, near a fully prepared operating room, and should be administered to the infant without any anesthesia. The barium must be allowed to flow in extremely slowly, since the intestine is fragile and edematous and may be easily torn. When given under the fluoroscope, it is easily possible to know at what point the barium ceases to ascend the intestine. In many instances the column of barium will, after a short delay, fill the loop of intestine that is the site of the invagination and thus make operative intervention unnecessary. It is advisable to give the enema as early as possible, although it is occasionally justifiable to use this method after an invagination has existed from twenty-four to thirty-six hours. Finally, the author believes that in those cases in which the diagnosis of invagination is doubtful because the symptoms are not all present, the barium enema may establish the diagnosis during the first few hours of its existence and before the appearance of the bloody stools. Even when this method fails as treatment, it will permit operating on the nursling while it is still in good condition.

**Late Syndrome of Penetrating Wounds of Skull.**—

According to Targowla, the most important late symptoms resulting from penetrating wounds of the skull sustained in the war of 1914 to 1918 consist in the triad of hemiplegia, epilepsy and changes of mental state. The changes in mental state constitute the worst of these late symptoms from the standpoint of the individual, the family and society in general. The severe headaches, dimness of vision, intolerance to noise and other sensory phenomena, and the vertigo are important elements in the development of abnormal mental states of this nature. Extreme irritability, excessive emotion, feelings of inferiority and intellectual deterioration are the important end results.

## Presse Médicale, Paris

44: 1433-1448 (Sept. 12) 1936

\*Calcium Content of Cardiovascular System in Experimental Hyperparathyroidism. R. Leriche, A. Jung and S.-M. Duperuis.—p. 1433.  
Registration of Electrical Activity of Brain. A. Denier.—p. 1436.

**Experimental Hyperparathyroidism.**—Leriche and his colleagues report the result of a chemical and histologic study of the heart and blood vessels in experimental hyperparathyroidism. They gave injections of parathyroid extract to twenty-five young rats and fourteen rabbits. The extract used was that of Collip or Byla. Injections were made subcutaneously and varied in amounts of from 2 to 20 units daily. They were continued from two days to four and one-half months. The animals were fed a diet without restriction. Injection of Collip's parathyroid extract in young animals caused a considerable retardation and arrest in growth and killed a fairly large proportion of young rats. The adolescent rats withstood it better. The Byla extract caused much less arrest in growth and allowed longer survival periods. The entire heart of each was studied after removal of the blood. The vessels studied were the thoracic and the abdominal aorta and the femoral arteries. The animals were killed the day after their last injection. These studies showed that the quantity of calcium in the heart

doubles after six daily injections of Byla's parathyroid extract. The calcium content of the heart reaches four times its normal value after four daily injections of Collip's parathyroid extract in the young rats. The same doses have no appreciable effect on the adolescent rabbits. The effect on the heart appears to result from the four first injections. If injections are continued for a longer period, the calcium content of the heart returns to practically normal. The calcium content of the aorta of the young rat reaches from two to four times its normal value after prolonged injections of extract, while in the adolescent rabbit from four to fifteen doses rarely caused a doubling of calcium values. It may be concluded from these observations that experimental hyperparathyroidism produces an increased calcium content of the heart and arteries which can be demonstrated both chemically and histologically. The quantity, the quality and the duration of the injection all affect the degree of hypercalcemia. The animal used and its age also appear to influence the course taken. Apparently, however, even after prolonged injections, the calcium deposit remains raised in the arteries, although it may have returned to normal in the myocardium.

## Helvetica Medica Acta, Basel

3: 507-624 (Sept.) 1936

Vicious Circle of Colon and Secondary Megacolon of Isolated Loop in Transversosigmoidostomy. C. Henschen.—p. 507.

So-Called Lymphatic Reactions: Contribution to Glandular Fever. A. Studer.—p. 560.

The Changing Picture of Diabetes Mellitus. A. Schüpbach.—p. 573.

\*Rôle of Gastro-Intestinal Tract in Hematopoiesis and in Anemia. O. Naegeli.—p. 581.

**Treatment of Edema.**—Löffler states that treatment of edema is no more than treatment of a symptom. Its removal, however, serves not infrequently to break the vicious circle by relieving the load on a diseased heart or by enabling the tissue fluids to return to the general circulation. Cardiac therapy is frequently identical with the therapy of edema. The treatment of the latter, however, is as a rule an indirect treatment only of the cardiac condition. Treatment of the heart assumes a primary importance in the treatment of cardiac edema. It is of no value in edema of nephritic or thyrogenous origin. Mercurial diuretics are indicated in cases in which edema is the prominent symptom. They are likewise indicated in cachectic edema. They are not to be used in the presence of renal insufficiency. While urea derivatives are the diuretics of choice in nephroses, mercurial diuretics may be employed as well and deserve consideration as such. Treatment along etiologic lines is indicated in cases of nephroses in which syphilis, tuberculosis or other chronic infection is a factor. Despite the advances in the treatment of acute nephritis, the appearance of edema cannot always be prevented. The effect of hunger and thirst therapy of acute nephritis is directed not so much against the edema as to insure the sparing of renal and adrenal functions. There exists no need for more diuretics. It is important to remember that rest in bed and limitation of fluid intake are imperative in the treatment of every form of edema.

**The Gastro-Intestinal Tract and Hematopoiesis.**—The part played by the gastro-intestinal tract in hematopoiesis is strikingly demonstrated in the case of pernicious anemia. The relationship, however, is far more complicated than was at first believed. It can be definitely stated that insufficient absorption of iron can lead to iron deficiency and that deficient absorption of still other substances may likewise produce anemia. The anemia of deficiency diseases is easily understood, since all the substances necessary for the building processes are, with the exception of oxygen, introduced into the organism by way of the stomach. Differentiation of various types of anemias has an important clinical and therapeutic significance. Naegeli wishes to emphasize that the gastric and liver substance is effective in pernicious anemia only. In contradistinction to the earlier view, this substance represents an antipernicious rather than an antianemic principle. The author has never observed in his clinical material a definite effect from liver or gastric substance feeding or a reticulocyte crisis in any of the anemias save that of the pernicious anemia.

**Prostatic Test.**—Longo states that gentle massage of the prostate (three or five minutes in a patient with a fasting stomach) results in producing leukocytosis if there is chronic or subacute inflammation of the structure. The test is positive (production of leukocytosis) in prostatic inflammation whether or not associated with pathologic conditions of the tonsils and also in the latter conditions, whether or not associated with the former. The test is contraindicated in acute prostatitis. It is of value in the diagnosis of prostatic inflammation and it shows a possible relationship between disease of the prostate and of the tonsils.

**Dry Blood Test in Diagnosis of Syphilis.**—Dahr's modified technic of the Chediak test for the serodiagnosis of syphilis was reported in the *Münchener medizinische Wochenschrift* 81:1723 (Nov. 8) 1934 (abstr. THE JOURNAL, Jan. 12, 1935, p. 166). The test is made with one drop of dry blood. Pignoli used it in 250 cases of syphilis and in 125 nonsyphilitic cases. The Chediak modified test has the same sensitivity of the Wassermann and Meinicke second clarification tests in primary and secondary syphilis and in neurosyphilis. It is much more sensitive than the Wassermann and Meinicke tests in tertiary syphilis, in congenital syphilis and especially in latent syphilis. The test does not give specific results in pregnancy, in the puerperium or in the blood of new-born infants. The author emphasizes the advantages of the test, especially its rapidity, simplicity, low cost and reliability. He advises systematic performance of the test for diagnosis of latent syphilis in women in maternity hospitals, new-born infants in asylums, patients in ambulatory clinics and, in emergencies, for blood transfusion. The test is one of orientation, the results of which are to be verified by those of other serologic tests.

- Intercurrent Eclampsia: Expectant Treatment; Results in One Case. J. Dixon.—p. 2291.

**Calculous Chronic Cholecystitis.**—Malamud states that chronic pain of the right iliac fossa is a frequent symptom of calculous chronic cholecystitis. The pain may be accompanied by hepatic colic pain. It is intensified and gives a picture of acute appendicitis during aggravation of cholecystitis. In cases of this nature it is advisable to make clinical, chemical, biologic and roentgen examinations in order to find out the condition of the gallbladder before resorting to appendectomy. If the condition of the patient is grave, it is advisable to perform an appendectomy, making the incision large enough to be able to examine the gallbladder systematically. The appearance of a macroscopically normal appendix and of a pathologic condition of the gallbladder, especially acute cholecystitis and calculi, indicates cholecystectomy immediately after appendectomy. Two cases of calculous acute cholecystitis with a syndrome of acute appendicitis are reported.

- \*Diagnosis and Indications of Operation in Acute Mastoiditis. A. M. Cavazzutti.—p. 928.

**Acute Mastoiditis.**—Cavazzutti states that, from the first days of acute suppurative otitis media, a mastoid reaction takes place. According to local and general factors, the mastoid reaction may regress within a week or become more intensified as mastoiditis complicates otitis. In the latter case mastoiditis completely develops in twenty-one days. The diagnosis of mastoiditis is made by the persistence and intensification of the symptoms of the mastoid reaction after the first week; external inflammation in the mastoid region (differentiated from the early mastoid reaction by the time of appearance of the inflammation in relation to the duration of the disease), persistence of deep arterial pulsation (which indicates the persistence of empyema), persistence of neuralgic pain irradiated to the corresponding trigeminal territory, lowering of the posterior superior wall of the external auditory canal and destruction of the mastoid bone, verified by roentgen examination of the bone. Fever, especially if high, beyond the first week is an unfavorable symptom which, alone or with other symptoms, may indicate an operation. Operation must be performed in all cases of acute mastoiditis in which the diagnosis is confirmed, but especially in mastoiditis complicated by subcutaneous abscess of the mastoid region and otitis of three weeks' duration with inflammation of the surface of the apophysis, or without apophyseal inflammation, but with subjective and objective symptoms of an unfavorable evolution and no tendency to a regression of the disease. Grave complications, whether or not fully developed, indicate immediate operation, regardless of the duration of the disease. Systematic performance of an operation during the first week of otitis to prevent the development of mastoiditis is inadvisable. Indications for operation during the first and second weeks depend on the evolution of the disease and the development of grave complications. All cases of otitis the evolution of which is not favorably modified by the fourth week are indications for an immediate operation, regardless of the absence of alarming symptoms. In cases in which the diagnosis is already confirmed but in which there are doubts as to the advisability of operating, the decision is based on the following principle: Operation for mastoiditis which could evolve satisfactorily without surgical intervention is better than losing patients who might have been saved by it.

- \*Diagnosis and Differential Diagnosis of Pulmonary Abscess in Older Children. S. Müller.—p. 224.

**Epiphyseolysis as Birth Injury.**—Chiari reports the histories of two cases of birth injury in the region of the elbow; namely, an epiphyseolysis at the lower end of the humerus. In the first case the origin of the epiphyseolysis was obscure, for there was no record of a severe trauma during birth nor were there indications of a congenital inferiority of the skeleton. In the second case, which lies thirteen years back, the origin is more clear, since there was a transverse position, and the delivery was terminated by version and extraction.

**Pulmonary Abscess in Older Children.**—According to Müller, pulmonary abscesses are not as rare in older children as is generally believed. In adults as well as in children there

are considerable diagnostic difficulties in the differentiation from interlobar empyema, sacculated empyema and tuberculous cavities. The author first describes the clinical histories of two boys, aged 10, who were subject to bronchial asthma and who, following a pneumonic process, developed a pulmonary abscess which was cured in both cases following the surgical opening of the abscess. In these cases the physical as well as the roentgenologic examination revealed the pulmonary abscess. Then follows the history of a boy, aged 16, who had a severe diabetes and who developed a pulmonary abscess. The observations in this case suggested a tuberculous disorder, but the necropsy revealed a pulmonary abscess. The differentiation was difficult in this case. Tuberculosis as a rule does not present an isolated focus of decomposition in an otherwise intact lung, but tuberculous foci must be expected in other parts of the lung; and this was the case in this diabetic patient. In addition to a shadow in the right upper lobe, there was a focus in the left lower lobe. The necropsy revealed, however, that this focus was a bronchopneumonic one. The author further reports a case of spontaneously cured sacculated hydropneumothorax in a boy aged 7. He thinks that the hydropneumothorax, which was accompanied by bronchopneumonia and bronchiectasis, resulted from the bursting of an emphysema vesicle. In discussing the differential diagnosis of this case, he says that the boy presented at first the signs of pneumonia, and this diagnosis was roentgenologically corroborated. However, after the pneumonia had run its course, roentgenoscopy revealed in the left side of the thorax a fluid level and above it an air vesicle. The patient felt comparatively well and had no sputum, and thus an intrapulmonary process could be excluded. Finally, the author reports two cases of interlobar empyema (in a boy aged 8 and in an adult aged 43). Both these cases healed spontaneously following perforation of the empyema into the bronchus. In the case of the adult a tuberculous process could be excluded, in view of the rapid development and prompt disappearance of the process and the lack of scar formation. However, it was at first difficult to decide whether the process was an interlobar empyema or a pulmonary abscess in juxtaposition to the interlobar cleft. Several roentgen exposures and other aspects of the case finally disclosed it to be a parapneumonic and metapneumonic empyema in the middle interlobar cleft.

- \*Causes of Death in High Intestinal Obstruction in Experimental Animal. J. Bottin.—p. 705.

**Thyroid Activity and Fracture Healing.**—According to Eitel and Lexer, clinical observations have established the favorable effect of thyroid substance on the healing of fractures. It was believed that this effect was brought about by an increase in the hyperemia about the fractured ends and that this hyperemia was caused by the activity of the thyroid secretion. To test the correctness of this assumption the authors experimented with hyperthyroidized animals in which they produced subcutaneous fractures. They found that the hyperemia took place earlier and lasted longer in animals treated with thyrotropic hormone. They also found that thyroxine acted in a similar manner. The effect produced by both substances is based on their ability to raise the metabolism. They likewise had undoubted clinical demonstration of the stimulating effect of the thyrotropic hormone on delayed union of fractures.

**Death in High Intestinal Obstruction.**—Bottin concludes, on the basis of numerous animal experiments, that death in experimental high intestinal obstruction is caused by two main factors: intoxication and water and salt deprivation. Infusions of large amounts of physiologic solution of sodium chloride delay death in animals with a high intestinal obstruction by seven and, at times, fifteen and even twenty-one days. Only the resection of the duodenal portion of the pancreas is capable

of prolonging the life of the experimental animal up to the thirtieth day. The author has utilized the method of exchange of blood between an animal with experimental high intestinal obstruction and a normal animal since 1931. Exchange of blood between a dog first deprived of water and salt for sixteen hours and a dog severely damaged by intestinal obstruction led in the former to total anuria and death without other organic changes. An animal not deprived of water and salt tolerated the blood exchange a longer time. If the animal with high intestinal obstruction was first given a copious infusion of physiologic solution of sodium chloride, the recipient, though prepared with deprivation of water and salt, suffered little from blood exchange, provided the donor has not been rendered too toxic by the obstruction. After seventeen days of obstruction, the blood exchange was fatal to the recipient unless he was treated on the interruption of blood transfusion with copious transfusion of physiologic solution of sodium chloride. Two animals deprived of water and salt suffered no damage when subjected to exchange of blood. A healthy dog, and even one deprived of water and salt, will tolerate the blood of a dog with high intestinal obstruction as long as the latter is still in good condition. The removal of the duodenal portion of the pancreas of the dog with high intestinal obstruction improved the recipient's chance to survive. Transfusion of blood from a dog that had had a high intestinal obstruction for twenty-five days was always fatal to the recipient. Toxic manifestations became evident soon after the intestine had been obstructed. The ensuing loss of water and salts interferes with the processes of detoxification. The removal of the pancreas, the chief focus of intoxication, prolongs the life of the experimental animal up to a certain point, beyond which there develop toxic substances from other sources.

- \*Experimental Studies on A Avitaminosis. M. Frank.—p. 1077.

**Apparent Change in Blood Group.**—Neumann and Neugebauer discuss the history of a patient with chronic lymphatic leukemia in whom, by means of the test serums that are available on the market, the blood group AB had been determined. In repeated transfusions it was noted that the patient tolerated blood from B donors well, whereas he developed fever in response to the transfusion of A blood. It was decided to determine the blood group once more and at this time only the B agglutinin could be detected. Repeated examinations with other test serums again and again revealed only the B agglutinin. This case demonstrates that for the determination of blood groups merely the use of purchasable test serums is inadequate. The authors emphasize that, in every case of blood group determination, the serum of the patient should be tested as well. When the patient whose case is reported later required further blood transfusions, a donor of the so-called universal group (O) was taken. This transfusion, however, caused a severe hemolysis, which in turn resulted in hemoglobinuria. In the subsequent hemolysis cross test the erythrocytes of the patient were almost momentarily hemolyzed. Thus this case demonstrates the absolute necessity of the hemolysis cross test in blood transfusion, particularly if a so-called universal donor of group O is to furnish the blood. Following a discussion of the serologic aspects of this case, the authors emphasize that in the various types of anemia the group O should be used only if it represents the identical group. Moreover, in any case of blood transfusion the use of blood of the same group is always the method of choice.

**Calcium-Quinine Treatment of Pneumonias During Childhood.**—Sebian reports that the calcium-quinine therapy of pneumonia was used in thirty cases at the children's clinic of the German University in Prague. The medicament was always administered by intramuscular injection in daily doses

of 5 cc. In fourteen cases of lobar pneumonia the calcium-quinine therapy was found to effect neither a reduction in the duration of the disease nor any other improvement. In the sixteen patients with bronchopneumonia it produced much better results. To be sure, in cases of bronchopneumonia in which the calcium-quinine was not given before the fourth day, the disease took the usual course; but in cases in which it was given within the first three days, the fever fell critically on the following day and the general condition of these patients was favorable.

**Experimental Studies on A Avitaminosis.**—In summarizing his experimental studies, Frank states that with the same deficiency diet rats develop the symptoms of A avitaminosis sooner during the early part of the year than during summer and early fall. The vitamin A is subject to seasonal fluctuations in these animals. It is lowest in the late fall and winter months, begins to rise in February, and reaches its highest values in the summer months, as the result of the presence of large amounts of the vitamin or of the previtamin in the diet. The beginning rise in the vitamin content during February cannot be explained by a greater intake in the food and must be due to other than alimentary factors.

### Ray Treatment and Surgery in Fibromyomas of Uterus.

—Claude Béchère points out that Antoine Béchère said in 1912 that roentgen therapy can be tried in nearly all fibromyomas of the uterus, without consideration of form and size of the tumor and of the age of the patient. To be sure, a correct diagnosis of fibroma is an absolute requirement. The author thinks that, if the height of the tumor above the symphysis is regularly measured at intervals of eight days an erroneous diagnosis will soon be discovered and the ray therapy can be interrupted and an operation can be done. In an evaluation of the advantages and disadvantages of ray treatment and surgical treatment, the author lists the following factors as the advantages of roentgen therapy: absence of mortality, absence of pain and no interruption in the working capacity. The disadvantages of roentgen treatment are the possibility of a diagnostic error, incomplete reduction of the tumor and possibility of later complications. In discussing surgical treatment, the author mentions as the chief advantages that it verifies the diagnosis, that it makes a myomectomy possible, that it permits the complete removal of a tumor no matter how large and that it permits a radical treatment which will prevent later complications. However, these distinct advantages involve just as great disadvantages; namely, mortality, pains and interruption of the working capacity. Further, the author gives his attention to the indications for roentgen therapy as well as for operation and then discusses the complications that arise during and after treatment. In the difficult differential diagnosis of the uterine hemorrhages after completion of the treatment, the persistence or cessation of hot flushes is an important symptom. The author says that Antoine Béchère directed attention to this symptom and demonstrated that it permits a decision as to whether the hemorrhage is only a return of the menstrual flow or an abnormal metrorrhagia. Thus it will be known whether the irradiation should be resumed or avoided or whether a secondary carcinoma of the corpus uteri should be searched for.

**Total Roentgen Therapy.**—Belot points out that total irradiation is possible only as distant irradiation. To be sure, the two terms should not be confused, since distant irradiations include all those that are given from a distance of more than 50 cm. In total roentgen therapy it requires a distance of about 3.5 meters in order to obtain a uniform irradiation for

an adult of average size. The total roentgen therapy is advisable for disorders that involve the entire organism, for instance, diseases of the blood and of the hematopoietic organs, also for dermatoses, such as erythrodermias, certain forms of generalized edema, pruritus, mycosis fungoides and the lymphocytomas of the skin. The hardness of the rays and the filtration that is to be used in each case must be determined on the basis of the depth of the disease process. In diseases of the blood, a hard irradiation is required which, in order to reduce the intensity, is filtered to a high degree of homogeneity. In dermatoses, on the other hand, in which the irradiation of the deeper tissues is to be reduced to a minimum, soft rays are used. The author applied the total roentgen irradiation usually with the roentgen tube high up, the patient lying on a mattress on the floor. After discussing certain details of the technic, he gives his attention to the indications for the total roentgen irradiation. He admits that these are not strictly defined as yet. So far, it is advisable in only a limited number of disorders, but in these it is definitely superior to the irradiation of only parts of the body.

### Wiener klinische Wochenschrift, Vienna

49: 1245-1272 (Oct. 9) 1936. Partial Index

- Clinical Significance of Fat Embolism. R. von Oppolzer.—p. 1245.
- Sleep and Hibernation. H. Hoff.—p. 1248.

- Effect of Work on Psychic State. J. Aiginger.—p. 1256.
- Roentgenology and Hypophysis. A. Schüller.—p. 1259.

**Spontaneous Pneumothorax.**—According to Schick there exist, besides the traumatic variety, two distinct types of spontaneous pneumothorax, the symptomatic and the idiopathic. Symptomatic spontaneous pneumothorax may develop in the course of any destructive pulmonary lesion. It is observed most frequently in tuberculous disease of the lung (90 per cent) but also in gangrene, abscess, infarct or tumor of the lung. The author calls attention to the occurrence of the so-called benign or more correctly idiopathic spontaneous pneumothorax developing in the absence of signs or symptoms of any disease process in the lung. Because of the absence of pulmonary signs and the radiation of pain into the upper part of the abdomen or the cardiac area, the onset of this form of pneumothorax may be confused with an attack of angina pectoris. Days later there may develop a tension pneumothorax with displacement of the mediastinal structures and dyspnea. It has been observed predominantly in younger persons of the male sex. A tendency to recurrence and a strong familial predisposition were noted. The prognosis is almost always good. According to the author, B. Fisher was first to call attention, in a recent communication, to the existence of peculiar emphysema-like structures in the pulmonary apexes which he had observed in necropsies. He believed that the rupture of these was responsible for the origin of so-called idiopathic spontaneous pneumothorax. Fisher believed these structures to be the result of a chronic inflammatory process giving rise to localized atrophy of the alveolar tissue, to compression of bronchioles by proliferating connective tissue, and to a peculiar valve formation at the base of such vesicles through cicatricial contraction. A somewhat different view is advanced by Selminke and by Kjaergaard, who regard congenital pulmonary cysts as the etiologic factor. The rupture of a superficially located cyst or cysts gives rise to pneumothorax. They regard these cysts as developmental congenital anomalies of pulmonary alveoli. The author reports one case from the clinic of Julius Bauer in Vienna in which he had the opportunity to demonstrate on the basis of clinical data and roentgenologic peculiarities the pulmonary cyst or apical cicatricial vesicle (B. Fisher) as the cause of an idiopathic spontaneous pneumothorax.

**Traumatic Fat Atrophy.**—According to Rosenberg and Berliner, Depisch was the first to describe, in 1926, local disappearance of fat in diabetic patients on insulin treatment. Depisch named it "insulinlipodystrophy." The one observation reported in common by several authors was that the lesion occurred much more frequently in women than in men. Two possibilities were advanced as to its etiology. One was that of a specific as yet unexplained hormone action of insulin,

and the other that of a chemical or traumatic damage of the act of injection. Graham and Carmichael believed that a certain amount of the lipolytic ferment in the insulin, because of its derivation from the pancreas, was responsible for the local fat necrosis. The presence of such a ferment in the insulin, however, was not demonstrated. Avery believed the necrosis to be the result of a long continued local inflammatory process resulting from injections. This view was not confirmed by histologic studies. The authors in their study of the subject found that among 4,000 diabetic patients treated on insulin therapy the incidence of local fat atrophy was less than 0.5 per cent. The predisposition on the part of the female sex was marked. There were twenty-seven of the female and five of the male sex. The age of the patient and the duration of diabetes played no part in the incidence. Duration of the injection treatment, however, was an important factor. Fat atrophy was not seen in patients who received injections less than three months. In a study of 1,000 consecutive patients admitted to a dispensary, the authors observed the same phenomenon in four nondiabetic patients and in one with mild diabetes. None of the five received injections of any kind. Four were women. In three the area of dystrophy on the thigh came in contact with the rim of a tub in which the patients did their daily washing of clothes. Because of a similar frequency in the groups and the clear evidence of trauma in the second group, the authors are inclined to ascribe the phenomenon of local fat atrophy to oft repeated trauma rather than to some local or general effect of insulin.

Phrenico-Exeresis. A. G. Gilman.—p. 65.

**Evaluation of Phrenico-Exeresis.**—Of 220 patients with pulmonary tuberculosis subjected to phrenico-exeresis at the Sanatorium Livadia, Gilman was able to make a follow-up study of ninety-four. He did not find many deviations from the normal course in the phrenic nerve. Those encountered in the course of the operation are due to the position of the patient's neck and to altered relationships of the tissues brought about by operative manipulations. Anatomic studies alone were to be relied on for the study of anomalies of the course of the phrenic nerve. The extent of the nerve excised varied from 10 to 40 cm. There is a relationship between the degree of paralysis of the diaphragm attained and the therapeutic effect. Clinical cure was obtained in 13.8 per cent of the patients, improvement in 29.8 and no change in the condition of 15.9; 11.7 became worse and 28.8 died in from one to six years. The author believes that the operation of phrenico-exeresis is indicated in isolated lesions of the base, with or without tissue destruction, but with tubercle bacilli in the sputum; in recent limited processes of other portions of the lung when induction of artificial pneumothorax is not possible; in the presence of blood spitting or hemorrhages, and when artificial pneumothorax cannot be induced and thoracoplasty is contraindicated because of the condition of the opposite lung. Phrenico-exeresis has no permanent effect in diffuse chronic cirrhotic lesions with cavities, in which the operation has only a palliative character. Phrenico-exeresis is not to be recommended as a preliminary stage to thoracoplasty. In the presence of adhesions of the base and apical involvement, phrenico-exeresis will aid a partial artificial pneumothorax in bringing about partial collapse of the lung and of a cavity. Phrenico-exeresis cannot be considered a substitute for thoracoplasty in cases in which the latter is indicated. Phrenico-exeresis may give a good result in extensive chronic lesions if combined with a prolonged sanatorium management. The author advises alcoholization of the phrenic nerve in cases in which a satisfactory effect may be anticipated in from four to six months or when total paralysis of the diaphragm is not desirable because of the condition of the opposite lung.

Attempt at Serum Treatment of Chicken Leukosis. J. Engelbreth-Holm, A. Rothe Meyer and E. Uhl.—p. 915.

**Tumors Originating from Striated Musculature.**—Engelbreth-Holm states that benign rhabdomyomas with striation are found practically only as congenital tumors in the heart and, because of their localization, have a grave prognosis. Besides, in striated musculature rhabdomyosarcomas most often appear in the urogenital tract, fifty such cases being known (Geschichter). He has found thirty-six cases of rhabdomyosarcomas in striated musculature in the literature; of the twelve in which sex and age were named, eight were in male and four in female patients, aged from 7 months to more than 50 years. Rhabdomyosarcomas are highly malignant, with marked invasive growth, frequent metastasis and usually recurrence after attempted extirpation, and are little or not at all sensitive to irradiation. Macroscopically they present the fishmeat appearance typical of sarcomas; microscopically the picture is polymorphic but there are always more or less numerous larger irregular cells with striated fibrils. Degenerative phenomena are frequent. The case described was that of a man, aged 75, in whom gradually developing total paresis of the left facial set in two years before admission, with an increasing swelling on the left side of the neck, impaired hearing in the left ear and pronounced loss of weight. The swelling was firm, nodular, not tender, and from it a firm nodular strand extended into the left supraclavicular region, where a gland of the size of a pigeon's egg was found, together with smaller glands. In the left submaxillary region was a gland of hazelnut size. The tumor seemed to diminish slightly on roentgen treatment, but in three weeks metastases to the throat were noted. Rapid aggravation followed, symptoms of cardiac insufficiency appeared and the tumor of the neck increased in size. Death occurred seven weeks after admission. The histologic diagnosis was rhabdomyosarcoma. The author says that, while primary tumors in striated musculature must in some cases develop from broken-off germs, malignant myosarcomas can develop from "normal" muscle tissue as the result of exogenic influence.

\*Fatal Intoxication with Trichlorethylene in Man with Scrofula and Miliary Tuberculosis: Medicolegal Casuistic Number 5. E. H. Hansen.—p. 862.  
\*Investigations on Occurrence of Hemolytic Streptococci in Throat in Patients With and Without Disturbances in Upper Respiratory Tract: Their Significance in Origin of Angina. H. Rasmussen.—p. 864.

**Fatal Intoxication with Trichlorethylene.**—Hansen says that this case is the first instance of fatal trichlorethylene poisoning to be reported in Denmark. The patient was one of two men occupied, mostly in a reclining position, with clean-up work in the small space under the floor of the engine room of a motorboat, and exposed to the fumes from the room above, where trichlorethylene, heated to about 100 C., was being used in cleaning. The patient's resistance was undoubtedly lessened by the tuberculosis of the mediastinal glands and miliary spread in the lungs and pleura, liver and spleen disclosed on necropsy. The fellow worker, suffering from trichlorethylene intoxication, recovered after a protracted course.

**Hemolytic Streptococci in Throat.**—In sixty-one out of ninety-three patients with disturbances of the upper respiratory tract and eleven out of twenty-six without such disorders, hemolytic streptococci were found in the throat. Comparison of the results on admission and on discharge showed the streptococci to be inconstant. In this material nine cases of angina occurred; in all hemolytic streptococci were present in the throat, mostly in large numbers or in pure culture, and in half of the cases hemolytic streptococci had been established before the angina. Seven of the cases were from a large ward and two from a small one. Rasmussen says that, since nosocomial anginas mainly occur in large wards, the cause appears to be an exogenic infection and it is doubtful that the hemolytic streptococci are the active virus.

## HYPOPARATHYROIDISM

### THE TREATMENT OF CHRONIC CASES

R. H. FREYBERG, M.D.

R. L. GRANT, Ph.D.

AND

M. A. ROBB, M.S.

ANN ARBOR, MICH.

Hypoparathyroidism may occur spontaneously, the so-called idiopathic variety; more frequently, however, it follows operation for the removal of part or all of the thyroid gland. During such an operation the parathyroid bodies may be injured, their blood supply may be interfered with or they may be accidentally removed, and as a result of any of these mishaps a state of hypoparathyroidism may result. Fortunately, owing either to recovery from trauma to the glands or their blood supply or to hypertrophy of remaining parathyroid tissue, the state of hypoparathyroidism may be acute and easily managed, especially with the judicious use of parathyroid extract. However, not infrequently a state of postoperative hypoparathyroidism may exist and require constant treatment throughout the remainder of the patient's life.

Recently we have had an opportunity to study, extensively, two persons with chronic postoperative parathyroid tetany. Under carefully controlled conditions, we have measured the effect of various remedies frequently employed in the treatment of this condition. It is our purpose in this communication to present the data obtained and the principles of treatment suggested by this study, and to contribute an explanation for the "refractiveness" to parathyroid extract so frequently encountered when this hormone is injected over a period of time.

#### REPORT OF CASES

CASE 1.—L. R., a woman, aged 36, had a thyroidectomy in this hospital for exophthalmic goiter on June 24, 1929. The basal metabolic rate promptly fell to normal and has remained so ever since. June 28, 1929, tetany, with carpopedal spasm occurred. She was treated with parathyroid extract subcutaneously, and calcium lactate and very small doses of viosterol orally. Eight days later the concentration of calcium in the blood serum was 7.0 mg. per hundred cubic centimeters of serum, and it steadily increased until it was 10.7 mg. August 20, when she was discharged from the hospital. She was advised to eat a high calcium diet and to take 2 Gm. of calcium lactate orally, and 0.5 cc. of parathyroid extract, subcutaneously each day.

She continued to feel well until January 1930, when she contracted influenza. She ceased taking the parathyroid extract

at this time. In October 1930 her finger nails dropped off. They soon regrew, but they dropped off on two more occasions. In November 1930 she noticed dimness of vision, which became progressively worse, owing to the formation of cataracts. In February 1931 she began having frequent attacks of tetany, and almost constant pain and stiffness of the muscles of the extremities. She was successfully treated, elsewhere, with a high calcium diet, 6 Gm. of calcium lactate, and 3 Gm. of ammonium chloride orally, and 1 cc. of parathyroid extract subcutaneously daily. She continued on this plan of treatment until October 1933, when she again came to the University Hospital complaining of muscle cramps and pain in the extremities. She exhibited a brisk Chvostek's sign. The serum calcium was 5.4 and the serum phosphorus 7.3 mg. per hundred cubic centimeters. She was treated with a high calcium diet, from 3 to 12 Gm. of calcium lactate and small amounts of viosterol orally and from 1 to 2 cc. of parathyroid extract subcutaneously each day. The improvement, however, was not as great as before and, on several occasions, injections of 10 per cent calcium gluconate were given intravenously to relieve painful muscle spasms. December 18 the serum calcium was 7.3 mg. per hundred cubic centimeters. The cataracts were removed and the patient was discharged, with the advice to continue the treatment instituted in the hospital.

In January 1934 dicalcium phosphate ( $\text{CaHPO}_4$ ) was substituted for the calcium lactate. Within a few days tetany occurred, which disappeared when calcium gluconate was taken instead of dicalcium phosphate. She was relieved of severe cramps and spasms, although the muscles of the extremities were stiff much of the time, so that she could not use her hands and arms well.

She returned again in July 1934, complaining of muscle cramps. Chvostek's and Trousseau's signs were present. The serum calcium was 6.1 mg. per hundred cubic centimeters. She failed to improve satisfactorily when treated as she had been during the previous hospitalization. When she was discharged, Aug. 17, 1934, the serum calcium was only 6.2 mg. per hundred cubic centimeters.

At home she became progressively worse, so that it was necessary to inject calcium chloride intravenously on numerous occasions, to relieve tetany. Jan. 9, 1935, she returned to the hospital. Carpopedal spasm was so severe that she was unable to use the hands. Sitting in a chair would precipitate cramps of the leg muscles. Chvostek's and Trousseau's signs were marked. The serum calcium and phosphorus were 4.8 and 7.1 mg. respectively per hundred cubic centimeters. Again treatment with high calcium diet, parathyroid extract, calcium lactate and small amounts of viosterol did not cause satisfactory improvement.

#### METABOLISM STUDIES

March 6 a study of the calcium and phosphorus exchange and serum concentrations was begun. The patient was fed the same diet day after day until June 7. This diet was rich in calcium, since it included 1,500 cc. of milk daily; the calcium-phosphorus ratio was 1.36. After a period of adjustment to the diet, the observations appearing in chart 1 were made. The excretion of calcium and phosphorus is charted in three day periods. At the beginning of each period, blood was removed for serum calcium and phosphorus determinations. The methods used have been described in a previous communication.<sup>1</sup>

From the Department of Internal Medicine, University of Michigan Medical School.

The authors are indebted to Dr. L. H. Newburgh for many helpful suggestions given during the course of this study.

1. Freyberg, R. H., and Grant, R. L.: A Study of the Calcium and Phosphorus Metabolism in a Verified Case of Pituitary Basophilism, *Arch. Int. Med.* 58: 213-228 (Aug.) 1936.

This study reveals the following significant facts: A high calcium diet (with 1,500 cc. of milk daily) alone caused no improvement. When 240 cc. of a 5 per cent solution of calcium lactate was taken there was a prompt rise in the serum calcium and a fall in serum phosphorus and distinct clinical improvement, with disappearance of tetany. The calcium lactate was then abruptly stopped, and inside of twenty-four hours the

with period 25, the standard preparation of viosterol (250 D) was used, 3 cc. (30,000 U. S. P.) being given daily. No change occurred.

Desiccated thyroid, 0.2 Gm. daily, administered from period 25 through 29, had no distinct beneficial effect.

Study of the calcium and phosphorus exchange was discontinued after period 29. The patient continued to receive the same type of diet, 240 cc. of 5 per cent solution of calcium lactate and 2 cc. of viosterol daily until June 19, 1935. On this day the amount of calcium lactate was doubled. No significant change in serum calcium or phosphorus or in the clinical condition resulted.

June 29, milk was omitted from the diet. No other change was made. The diet was thus made comparatively poor in phosphorus and calcium, but with the calcium lactate medication the intake of calcium was high while that of phosphorus was low—the Ca/P ratio being 5.3. After a period of adjustment to this new diet, the calcium and phosphorus exchange was again studied. Chart 1 shows the decrease in serum phosphorus and the rise in serum calcium that occurred with the change in the Ca/P ratio of the ingesta.

The patient was discharged from the hospital on this last plan of treatment. She remained well at home, until October 10, when she returned for further study.

From October 21 to November 4 the patient was fed a diet made as low in phosphorus as possible while still keeping it adequate in other respects. (Egg albumin was used as the chief source of protein. The daily phosphorus intake was calculated to be about 0.4 Gm.). The serum phosphorus fell slightly and the calcium rose (chart 2). The diet was then changed again to the "low phosphorus" type previously used (omission of milk, chiefly).

Parathyroid extract was again injected subcutaneously, in doses larger than previously used, and again it was of no value.

After the patient recovered from an acute infection of the upper respiratory tract (which affected the calcium and phosphorus metabolism unfavorably), 1.8 Gm. of magnesium carbonate was given daily for two weeks. The serum phosphorus decreased and the serum calcium first increased and then fell. It was thought that the patient was not benefited by this medication.

The effect of parathyroid extract injected intravenously was next studied, in a manner similar to that used by Ellsworth.<sup>4</sup> While the patient was receiving nothing by mouth but 200 cc. of water hourly, the effect of 1 cc. of the drug was measured

Chart 1.—Calcium and inorganic phosphorus metabolism during the first portion of the study of case 1. The exchange of these elements is represented by three day periods. Star indicates two days.

serum calcium had fallen to such a degree that the patient had a carpopedal spasm. Beginning with period 8, hydrochloric acid was given in large amounts with the hope that the absorption of calcium might be increased or that calcium would be liberated from the skeleton and thus raise the concentration of serum calcium. However, no benefit resulted. Beginning with period 10, a 10 per cent solution of calcium chloride was administered. It was thought that this acid-producing calcium salt not only would increase the calcium intake but might aid in absorption of calcium or in the liberation of this element from bony storehouses and would thus be of greater benefit to the patient than calcium lactate. When 30 cc. of this calcium chloride was given daily (supplying 1.16 Gm. of calcium), no benefit resulted. When the dose was doubled the serum calcium rose, but at a rate no greater than observed when less than the equivalent amount of calcium was supplied as calcium lactate; the serum phosphorus fell. The excretion of calcium in the urine increased, but there was no evidence of increased absorption. Calcium chloride was accordingly stopped, and 240 cc. of 5 per cent calcium lactate solution was given daily throughout the remainder of the first portion of this study.

Parathyroid extract was injected subcutaneously in 0.4 cc. doses daily through periods 18 and 19.<sup>2</sup> The patient was in no way benefited by it. Beginning with period 20, a large daily dose of irradiated ergosterol was administered. An especially concentrated solution<sup>3</sup> of viosterol was used, and an amount supplying 200,000 U. S. P. vitamin D units was given daily. There was a distinct rise in serum calcium and fall in serum phosphorus following this addition to the treatment. Beginning

by the quantity of phosphorus excreted hourly in the urine. Immediately after the drug was injected there was a distinct increase in urinary phosphorus, which continued through the four hour period of study (table 1). On the following day 4 cc. was injected intravenously. This amount caused almost

2. Throughout this paper, the dosage of parathyroid extract is expressed in cubic centimeters in order to avoid confusion that might result if the dosage were measured in units, since recently the unit strength of parathyroid extract has been changed.

exactly four times the urinary excretion of phosphorus during the same interval of time as did 1 cc. on the previous day. The concentrations of calcium and phosphorus in the serum were not significantly changed following the first intravenous injection; after the larger dose the serum phosphorus was slightly lower, and the calcium also lower. Further study of the effect of parathyroid extract injected intravenously was not made, because almost immediately after the second injection the patient had a reaction characterized by faintness and

\* The patient received nothing by mouth but 200 cc. of water hourly.

apprehension, rapid pulse and low blood pressure, followed by headache, extreme weakness and slight fever. Ten days later, severe generalized pruritus developed. This reaction was considered to be due to foreign protein. The parathyroid extract used was found to contain 0.4 per cent of protein by sulfosalicylic acid precipitation.

The effect of subcutaneous injections of parathyroid extract in amounts comparable to the intravenous doses was next tested in a similar way. The patient was fed a constant diet, in order that changes in phosphorus excretion might be significant. The urinary phosphorus decreased and the serum phosphorus increased during the period of therapy (table 2).

In January 1936 the last period of study was begun. A constant low phosphorus diet, a large amount of calcium lactate in 5 per cent solution, and 2 cc. of viosterol were given daily throughout this study. The daily urinary phosphorus excretion was measured in addition to the serum calcium and phosphorus determinations. It was observed (chart 3) that parathyroid extract injected intramuscularly was of no benefit. The effect of subcutaneous injections of a different preparation of parathyroid extract was then tested. The first trial seemed to benefit the patient. A subsequent trial showed it to be of no value, except possibly when given in very small doses. Later study showed that small doses also were valueless.

The disturbing effect of infection on calcium and phosphorus metabolism is again illustrated, especially during February 11-16, when the patient had a fever.

Lastly, the effect of frequent intravenous injections of calcium gluconate was tested. March 14, 9 cc. of a 10 per cent solution of calcium gluconate was injected twice daily, and on March 15 and 16, 10 cc. was injected three times daily. The serum calcium rose to only 8.4 mg. per hundred cubic centimeters and the serum phosphorus fell to 5.7 (chart 3). Most of the injected calcium was found in the urine of those days. In as short a time as four days most of the improvement was lost, illustrating the transient benefit of injected calcium salts.

CASE 2.—V. G., a woman, aged 35, had a thyroidectomy performed (elsewhere) in June 1929 for adenomatous goiter with hyperthyroidism. Following operation, progressive deafness and dimness of vision occurred, and her weight increased quite

rapidly. In February 1930 tetany began. In June 1930 she began taking "two tablets" of thyroid extract (? 0.13 Gm.) daily and thereafter noticed an improvement, especially in hearing. Vision gradually became worse and the muscle spasms more frequent. Since early in 1932, treatment had consisted of a high calcium diet, a calcium salt orally and at times intravenously, and tablets of parathyroid extract. On this plan of treatment she had no severe spasms, although most of the time her muscles were so cramped and painful that she was incapacitated.

Feb. 15, 1935, she came to the University Hospital. Bilateral incipient cataracts and Chvostek's and Trousseau's signs were present. The serum calcium was 7.8 and phosphorus 6.1 mg. per hundred cubic centimeters. A high calcium diet and 12 Gm. of calcium gluconate daily relieved the severe muscle spasm. The cataracts were then treated, after which the following studies were made:

#### CALCIUM AND PHOSPHORUS STUDIES

Throughout the first period of study a high calcium diet (1,500 cc. of milk daily) was fed. Ten Gm. of calcium lactate powder was given daily from March 26 through April 9, without benefit (chart 4). A solution of calcium lactate, 240 cc. daily, was then given with no noticeable improvement. Sixty cc. of a 10 per cent solution of calcium chloride was next administered daily. A slight increase in serum calcium and no change in serum phosphorus resulted.

Beginning April 23, 240 cc. of 5 per cent solution of calcium lactate was given and also 3 cc. of viosterol (30,000 U. S. P. vitamin D units daily). There was a prompt increase in serum calcium and decrease in serum phosphorus, accompanied by clinical improvement. Doubling the amount of calcium lactate caused no added benefit. Beginning May 7, 0.4 cc. of parathyroid extract daily was injected subcutaneously. The increase in serum calcium and the clinical improvement were striking. (The serum phosphorus change could not be noted because the value at the beginning of this therapy was not known.) When the parathyroid extract was stopped the serum calcium promptly decreased and the phosphorus rose. These serum values changed toward the normal when the parathyroid extract was again injected.

Chart 4 shows the low level of basal metabolism that existed when no thyroid medication was given and the prompt increase resulting from the administration of desiccated thyroid. During this study no significant relationship between the serum calcium and phosphorus and the rate of basal metabolism or thyroid medication was observed.

TABLE 2.—Ineffectiveness of Parathyroid Extract Injected Subcutaneously in Case 1 While a Constant Low Phosphorus Diet and a Constant Supply of Water Was Being Given

Date	Parathyroid Extract Subcutaneously, Cc.	Phosphorus in Twenty-Four Hour Urine, Mg.	Serum Calcium, Mg. %	Serum Phosphorus, Mg. %

21	4.0	26		
22	3.0	22		
23	None	23	7.9	7.1
24	None	12		

At the end of these studies the patient was discharged. She was advised to take a high calcium diet (1,500 cc. of milk daily), 240 cc. of 5 per cent solution of calcium lactate, 1 cc. of viosterol, 0.1 Gm. of desiccated thyroid orally, and 0.2 cc. of parathyroid extract, subcutaneously, daily. She remained in good health until December 1935, when she was unable to obtain all the medications (especially desiccated thyroid and frequently parathyroid extract). Muscle spasms and cramps recurred.

She returned to the hospital Jan. 27, 1936. Chvostek's and Trousseau's sign were present. Ten cc. of 10 per cent calcium

levulinate was injected intravenously for carpopedal muscle spasm. Further studies were carried out and are presented in chart 5.

She was fed a diet low in phosphorus and calcium (no milk) and 18 Gm. of calcium lactate in 5 per cent solution. No viosterol was given in order that the effect of parathyroid extract might be studied independent of any effect of this vitamin D concentrate. Parathyroid extract injected in 0.2 cc. doses subcutaneously during the first few days of study did

Chart 3.—Serum calcium and phosphorus and urinary excretion of phosphorus during the last period of study of case 1. A. U. R. I., acute upper respiratory infection.

not materially improve the patient, and it was thought that she might have become "refractive" to the extract. After a period without parathyroid extract, during which the serum calcium fluctuated around 8 mg. and the serum phosphorus rose slightly, it was found that 0.8 cc. of parathyroid extract daily injected subcutaneously caused a prompt increase in serum calcium and decrease in serum phosphorus, so that both values became normal within five days. When the amount of parathyroid extract was decreased, the serum calcium and phosphorus were again altered unfavorably. The patient was thus shown not to be refractive to the extract.

The same daily dose of parathyroid extract was then injected subcutaneously, in an amount sufficient to maintain the serum calcium and phosphorus values constant, and the calcium just at the low range of normal. Five Gm. of disodium acid phosphate in capsules was then fed daily, for five days. The serum calcium decreased. It appears that the administration of disodium acid phosphate diminished the effectiveness of the parathyroid extract.

The rise in serum calcium shown at the beginning of chart 5 might have been due to thyroid medication; but definite evidence that thyroid substance is of significant benefit to the calcium and phosphorus metabolism was not obtained later.

#### COMMENT

It should be noted that practically no calcium was excreted in the urine in case 1 when the serum level was below 7 mg. per hundred cubic centimeters (chart 1); at higher serum concentrations this element was excreted in normal amounts. This "threshold" phenomenon was found also by Albright and Ellsworth.<sup>5</sup>

Chart 3 shows the irregular excretion of phosphorus in the urine when the intake of this element was constant. We are unable to explain this.

The unfavorable influence of infection is repeatedly illustrated by case 1. In each case the menses were likewise found to have an unfavorable effect.

These studies serve admirably to indicate the considerations that are important in the treatment of chronic hypoparathyroidism. The data illustrate the benefit that is derived from certain remedies and point out certain things to be avoided if best results are to be obtained. Individual differences in patients naturally will govern details, but on the basis of observations made in these cases the fundamental principles for satisfactory treatment may be stated.

**Diet.**—It should be remembered that the serum of patients with hypoparathyroidism is characterized by a low concentration of calcium and a high level of phosphorus. To correct these abnormalities it is logical that the intake of calcium should be high and the intake of phosphorus low. To provide an abundant calcium intake it has been customary to prescribe a diet rich in calcium. The chief source of dietary calcium is milk, which is also rich in phosphorus; accordingly, all high calcium diets are high phosphorus diets. To provide a high calcium and low phosphorus intake, one must therefore feed a low phosphorus diet (which will also be relatively low in calcium) and supplement this with a calcium salt.

Albright<sup>6</sup> has produced evidence to show that the primary effect of parathyroid extract is on phosphorus, causing an increased excretion of this element in the urine; the effect on calcium appears to be secondary. It would naturally follow, then, that one should compensate for the most fundamental disturbance resulting from a lack of parathyroid hormone by providing a low intake of phosphorus. Further, if the phosphorus intake is kept low while the calcium intake is high, absorption of the latter element is facilitated.

Chart 4.—Serum calcium and phosphorus levels and the basal metabolic rate during the first portion of study of case 2.

Shelling<sup>7</sup> has demonstrated the advantage of low phosphorus diets to parathyroidectomized rats. Shelling<sup>8</sup> and Ellsworth<sup>9</sup> have emphasized the importance of low dietary phosphorus in the treatment of parathy-

roid tetany in human beings. The advantage of a low intake of phosphorus together with a high intake of calcium is repeatedly illustrated by our studies. When patient 1 took dicalcium phosphate instead of calcium lactate, tetany occurred. Again, when calcium lactate was abruptly stopped while the same high calcium diet continued (period 7, chart 1), tetany occurred within twenty-four hours, whereas later, when the diet was abruptly changed so as to lower markedly the phosphorus (and the calcium somewhat), and the same amount of calcium lactate continued, the patient was improved. In case 2 the unfavorable effect of disodium acid phosphate was observed (chart 5).

The diet can be made quite low in phosphorus by omitting milk. A still greater restriction of phosphorus can be obtained by omitting other foods rich in phosphorus (see food tables) and the avoidance of excess amounts of meat.

**Calcium Medication.**—An abundant intake of calcium is of the greatest importance. Except to relieve acute muscular spasm, the oral administration will suffice. For the reason already stated, calcium phosphate should not be used. Calcium lactate, gluconate and chloride are the salts most commonly employed. In our experience, calcium lactate gave results as good as or better than did the chloride, and it was less nauseating. From 12 to 18 Gm. of calcium lactate should be given daily; greater amounts were not found to be of added benefit. We feel that it is advantageous to give this medication in solution, in order to allow maximal absorption.

For the relief of acute muscular spasm, calcium should be injected intravenously. Ten cc. of a 10 per cent solution of the gluconate, levulinate or chloride injected slowly is usually sufficient.

**Vitamin D.**—Preparations of vitamin D have been reported to be without value by some investigators,<sup>10</sup> harmful by others,<sup>9</sup> and indispensable by still others.<sup>11</sup> Boothby<sup>12</sup> reports excellent results from the use of from two to three teaspoonfuls of cod liver oil (vitamins A and D) daily. Stacey<sup>13</sup> states that it is possible to maintain patients free from symptoms and with normal blood conditions with the use of large doses of pure vitamin D (calciferol).

In each of our patients there was definite benefit observed from the use of large doses of irradiated ergosterol (viosterol). The sharp change toward normal values for both serum calcium and phosphorus are especially well demonstrated by case 2 (chart 4). It must be emphasized, however, that for satisfactory results vitamin D should be given in large doses. In our tests, for a short time we administered 200,000 U. S. P. vitamin D units daily, although most of the time we used from 20,000 to 40,000 units. Other investigators<sup>14</sup> have used from 2 to 5 mg. of vitamin D (from 80,000 to 200,000 units) daily, with splendid results.

The manner in which vitamin D benefits these patients is not fully understood. Bauer, Marble and Clafin<sup>14</sup> have shown that vitamin D is effective only

when the intake of calcium is high, and that its chief effect was to increase the absorption of calcium from the intestine. In case 1 the fecal calcium was not noticeably decreased by the administration of viosterol, so that in this patient vitamin D must have been effective in another way.

**Acid Therapy.**—Aub<sup>15</sup> has reported improvement in the tetany of hypoparathyroidism from the administration of hydrochloric acid or ammonium chloride. Acid-producing substances are known to liberate calcium from the readily available stores.<sup>16</sup> Recently, Campbell<sup>17</sup> has reported distinct benefit from the use of large doses of hydrochloric acid in two cases of postoperative tetany with achlorhydria. He states that the increase in serum calcium was due in part, at least, to increased absorption from the intestine. No benefit resulted from the use of hydrochloric acid to patient 1, who also had achlorhydria.

Calcium chloride has been recommended because of its twofold effect: a source of calcium and an acid-producing substance. In neither of our patients, how-

Chart 5.—Serum calcium and phosphorus levels and the basal metabolic rate during the second study of case 2.

ever, was calcium chloride found to be of any advantage over an equivalent amount of calcium lactate, and it is more unpleasant to take.

**Magnesium Salts.**—Wenner<sup>18</sup> found that continuous oral administration of magnesium salts prevented tetany in parathyroidectomized animals. Ellsworth<sup>19</sup> administered magnesium carbonate to a patient with parathyroid tetany without striking benefit. In case 1 there was a rise followed by a fall in serum calcium and a decrease in serum phosphorus during the use of magnesium carbonate. We consider this salt to be of no value.

**Thyroid.**—Thyroid substance and thyroxine have been reported to exert a favorable effect on the disturbed calcium and phosphorus metabolism of hypo-

parathyroidism.<sup>15</sup> In case 1, in which the basal metabolism was normal, no benefit was derived from the use of desiccated thyroid. Thyroid substance improved patient 2 by correcting the hypothyroidism that existed, but that this drug was of benefit to the state of hypoparathyroidism is certainly not clearly shown. As a result of these observations we believe that thyroid substance should be used if hypothyroidism exists along with parathyroid tetany but that it is not particularly valuable otherwise.

**Parathyroid Extract.**—The most specific treatment for hypoparathyroidism is parathyroid extract, the use of which is true substitution therapy. Parathyroid extract injected subcutaneously or intramuscularly causes a prompt excretion of phosphorus in the urine and a lowering of the serum phosphorus, followed by an increase in serum calcium and the excretion of this element in the urine. In case 2, from 0.2 to 0.4 cc. of parathyroid extract daily, injected subcutaneously, caused the serum concentrations of calcium and phosphorus to become normal promptly. During the second period of study of this patient larger doses were necessary to maintain favorable serum calcium and phosphorus levels. This may have been due to the fact that viosterol was not being administered at this time.<sup>20</sup>

#### "REFRACTIVENESS" TO PARATHYROID EXTRACT

Unfortunately, the effect of parathyroid extract is completely lost in many persons after a period of continuous use. The subcutaneous and intramuscular injection of parathyroid extract from two different sources (Lilly and Parke, Davis & Co.) was shown to be of no benefit in case 1. This "refractiveness" to parathyroid extract has never been satisfactorily explained. The work of Collip,<sup>21</sup> to whom we are indebted for this therapeutic agent, suggests that refractivity may be due to a high concentration in the blood of a specific principle ("antihormone") having an effect opposite to that of the hormone. This investigator has very convincing evidence that the blood of animals injected chronically with certain pituitary fractions contains antagonistic substances which render these hormones ineffective. The existence of an anti-parathyroid hormone, however, has not been demonstrated.

Although patient 1 was refractive to parathyroid extract injected subcutaneously or intramuscularly, similar amounts of the same preparation injected intravenously caused an immediate outpouring of phosphorus in the urine, an effect shown by Ellsworth<sup>4</sup> to be specific for this hormone. This behavior certainly shows that in refractive states the tissues on which the hormone acts to accomplish its effect are not at fault; on the other hand it shows that the extract, when injected subcutaneously or intramuscularly, does not get to these tissues in a potent state. That the hormone is rendered ineffective by substances in the blood stream appears unlikely, in view of the quantitative response to intravenous injections.

For parathyroid extract to be effective when injected subcutaneously or intramuscularly, it must be absorbed into the blood stream and carried in a potent state to the tissue on which it exerts its effect. If absorption

from the tissues into which the extract is injected is interfered with, there will be a corresponding decrease or absence of effect. This may come about in a manner identical to that observed in the mechanism of local tissue immunity; i. e., with continued use of parathyroid extract, cells of the tissue into which it is injected may unite with hormone (just as cell products unite with antigens) and cause a localization of the hormone at the site of injection, where it is then destroyed. Fixation of the hormone at the site of injection, preventing absorption, would thus result in a state of "refractivity."

The occurrence in case 1 of an inflammatory reaction at the site of subcutaneous injection, much larger, warmer and more tender than resulted from injections of an equal amount of the extract in case 2, lends support to this explanation of the mechanism of "refractiveness."

Even though active when injected intravenously in patients otherwise refractive to parathyroid extract, this route of administration is not advised, because it is not practical and not without danger, as evidenced by our patient.

Many investigators urge that parathyroid extract be used in chronic hypoparathyroid states only for the relief of acute spasms, fearing the development of refractivity. When the disease can be controlled satisfactorily without its use, it would certainly seem wise so to do. The two subjects of this study could be sufficiently controlled without the use of parathyroid extract, so that they were free from tetany and enjoyed an active life. However, the serum calcium and phosphorus were never normal in patient 1, who was "refractive" to parathyroid extract, and in case 2 the concentrations of calcium and phosphorus in the serum were normal only when parathyroid extract was used. It is encouraging to note that the extract was apparently effective in case 1 for more than two and a half years, and in case 2 it was still effective after more than a year of almost continuous use.

#### SUMMARY AND CONCLUSIONS

Data obtained from extensive controlled studies on two patients with chronic postoperative hypoparathyroidism lead to the following statements regarding the treatment of this condition:

1. To compensate most satisfactorily for the altered state of calcium and phosphorus metabolism, the intake of phosphorus should be low and the calcium intake high. This can best be accomplished by feeding a low phosphorus diet (which will also be low in calcium) and large amounts of calcium salt, other than a phosphate. The commonly employed high calcium (milk) diet is undesirable because of its high phosphorus content.

2. A solution of calcium lactate, in amounts sufficient to provide from 1.5 to 2.5 Gm. of calcium daily, is in many respects the best method of administering calcium.

3. Vitamin D in large amounts is of definite value and should be given.

4. Hydrochloric acid and magnesium carbonate, as used, were not beneficial.

5. Thyroid substance should be administered, if hypothyroidism exists. Improvement in calcium and phosphorus metabolism that could be definitely attributed to thyroid medication was not observed.

20. Morgan, A. F., and Garrison, E. A.: Effect of Vitamin D and of Reaction of Diet upon Response to Parathyroid Extract, *J. Biol. Chem.* 85: 687-711 (Feb.) 1930.

21. Collip, J. B.: Recent Studies on Antihormones, *Ann. Int. Med.* 9: 150-162 (Aug.) 1935.

6. Although substitution therapy, consisting of the subcutaneous or intramuscular injection of parathyroid extract, is the most specific treatment, there are serious objections to the long continued use of this extract. If successful management can be accomplished without the use of parathyroid extract, it is advisable not to use it. These studies show that patients with severe chronic hypoparathyroidism can be maintained in a state of good, if not perfect, health by the treatment outlined, without the use of parathyroid extract.<sup>22</sup>

The effectiveness of parathyroid extract when injected intravenously into a patient who had become "immune" to the extract injected subcutaneously suggests that "refractivity" to parathyroid extract is due to a localization and destruction of the active principle at the site of its injection.

#### ABSTRACT OF DISCUSSION

DR. W. M. KETCHAM, Kansas City, Mo.: I have been interested in parathyroid diseases for the last nine years, during which time I have seen four children with chronic parathyroid deficiency and five adults, all of the adults suffering as the result of a goiter operation. I was impressed with certain facts after watching these patients over a year or two. All of them had a blood calcium ranging from 5 to 7 mg., and all the adults had a cachexia. The adults presented a cachexic state in spite of the fact that they had had goiter operations and that one might have expected myxedema. They were disturbed at night with cramps in their legs, forcing them to get up and walk. They had night sweats, which were drenching. Associated with this was a marked muscular insufficiency, which interfered with their daily work, even mild housework. It was believed at first that these patients would be benefited promptly by the use of calcium, but in the majority of the cases there were no results with calcium glutinate or calcium chloride given by mouth or intravenously. In gastric analysis of four patients an achylia was discovered. Hydrochloric acid was added to the diet but satisfactory results from the administration of both the hydrochloric acid and the calcium were not obtained. Because of the cachectic condition, these patients were placed on large doses of vitamin D, and in all except one good results were obtained when this was combined with hydrochloric acid and calcium. When it was certain that these patients had hydrochloric acid, large doses of vitamin D and fairly large doses of calcium up to from 50 to 75 grains (3.25 to 5 Gm.) daily were given. No better results with the administration of thyroid extract combined with parathyroid extract or the latter alone were obtained than did the authors. In one case no results could be obtained with any treatment and the authors' explanation is probably a correct one. But I have felt that every patient suspected of having parathyroid deficiency should be given calcium, hydrochloric acid and large doses of vitamin D, combined with parathyroid extract both hypodermically and by mouth.

DR. WILLIAM J. KERR, San Francisco: I should like to ask how many international units of viosterol, or vitamin D, were given in these large doses. My reason for asking the question about viosterol is that recently an elderly physician by mistake took 2,300,000 international units of vitamin D daily for eighteen days, when he developed a nausea, anorexia, weakness, increased thirst and polyuria, and then passed into a coma and died. The total quantity of material used was 3 cc. a day. So far as I know, this is the first case of acute poisoning from vitamin D in man resulting in death. There are some chronic cases, but one should be very careful to specify how much vitamin D one is using. The widespread use of highly concentrated doses of irradiated ergosterol is dangerous. It is among the most potent drugs known. It should not be put into the hands of the public and should not be prescribed indiscriminately by physicians.

22. Since these studies were made, we have had occasion to treat two other patients with chronic hypoparathyroidism, in the manner outlined, and the results have been excellent.

DR. R. H. FREYBERG, Ann Arbor, Mich.: I should wish to thank Dr. Ketcham for his discussion. It called to my mind several points. In reviewing the literature of the subject, I was struck with the relatively high incidence of hypoparathyroidism in women, especially in those cases which follow thyroidectomy. All our patients were women. Besides the unfavorable effect of infection on these patients, we have observed an unfavorable effect of menstruating on the calcium metabolism. Our first patient had achlorhydria, and I would point out that we did not measure any benefit to her from quite large amounts of hydrochloric acid, given along with a high calcium diet and no calcium salt. In reply to Dr. Kerr's question, at the beginning of the viosterol therapy we were using a preparation especially prepared for us by the Winthrop Chemical Company, which was ten times more potent than the usual preparation of viosterol. It was, in other words, 2,500 D. We gave amounts of this which were equivalent to from 160,000 to 200,000 U. S. P. units of vitamin D. That is a large dose. Our supply of that medication became exhausted, and throughout the remainder of the treatment we used the standard vitamin D, which was of the potency of 250 D, and we gave from 2 to 4 cc. of this preparation daily (from 20,000 to 40,000 U. S. P. vitamin D units). Since the data were compiled for this communication, we have had opportunity to treat two additional patients with chronic hypoparathyroidism following thyroidectomy, in the manner outlined, with splendid results.

## STUDIES IN SPLENOPATHY

### INTRODUCTION

ALLEN O. WHIPPLE, M.D.  
NEW YORK

*This and the following three articles deal with work at the Combined Clinic in Splenopathy of the Vanderbilt Clinic and the Presbyterian Hospital. The members of the staff are Drs. Allen O. Whipple, Kenneth R. McAlpin, William P. Thompson, Louis M. Ronsselot, Daniel N. Brown and Robert H. E. Elliott Jr.*

At the Vanderbilt Clinic and the Presbyterian Hospital the splenopathies are studied by a group of physicians and surgeons. Those splenopathies associated with specific blood pictures are studied by the group interested in the anemias and leukemias. The group of splenopathies under consideration is followed by the physicians and surgeons of the Combined Clinic.

The Spleen Clinic is one of several Combined Clinics working at the Vanderbilt Clinic and the Presbyterian Hospital. These Combined Clinics, made up of medical, surgical, pathologic and in some clinics radiologic departments, are engaged in the study of the so-called middle ground diseases. The patients referred to these clinics are studied by the group together, therapy is agreed on and, whether medical or surgical, the results are studied and evaluated by the same group. The workers in these clinics, from whatever department they may be, speak the same language and see eye to eye, and there are no therapeutic or other miracles among friends. There, as in no other clinic, pride and prejudice disappear and an honest integration of opinions and convictions results.

The Combined Spleen Clinic was organized about six years ago. Before 1930 we saw an occasional splenopathy, but in both the medical and the surgical services we were rather complacent about the classification of splenic disease and were rather satisfied with our results. As a result of studying these diseases together

Read at a symposium on diseases of the spleen before the New York Academy of Medicine, April 2, 1936.

in a group made up of members of the medical and surgical staffs we know more about the diagnosis and therapy of some of these lesions but are less certain about others and acknowledge our inability to classify many of the splenopathies and their associated lesions. During the last six years we have had a steadily increasing number of these patients referred to us from the Vanderbilt Clinic as well as from the city and neighboring communities, so that in our files we now have studied and are seeing in our follow up some 200 patients with the lesions classified in the accompanying table.

In our surgical laboratory we have sections of 102 spleens, and the majority of these have been removed since the Spleen Clinic was organized.

From the standpoint of the care of the patient, teaching and research—the three cardinal criteria of any clinic worthy of the name—the Combined Clinic has everything to recommend it. Certainly the patients get more careful study and discriminating opinion as to therapy, because it is the result of agreement among medical and surgical workers, based on mutual follow-up studies. Overconservatism or radicalism in therapy cannot dominate such a clinic.

*Classification of Total Cases Seen in the Spleen Clinic or by More Than One of its Members Since Its Organization Six Years Ago*

Total Cases	200
Disease	Case
Banti's disease	47
Purpura	43
Hemolytic jaundice	46
Unclassified splenomegaly	24
Sickle cell anemia	4
Syphilis of spleen	4
Gaucher's disease	4
Polycythemia	3
Splenomegaly with colitis	2
Schistosomiasis	14
Cooley's anemia	3
Osteosclerotic anemia	1
Lymphosarcoma	1
Unexplained hypochromic anemia	1
Hodgkin's splenomegaly	3

From the standpoint of teaching, one has but to ask our best graduate students, working as residents or fellows, to get a convincing statement that no other place affords such a rare opportunity to study "middle ground" disease in all its phases. In view of the fact that within the next five years astonishing advances will be made in graduate teaching in all large metropolitan centers, as a result of the establishment of qualifying boards in medical specialties, this type of clinic will be in the greatest demand for graduate study and should and will be organized in all large clinics, especially in the university clinics.

Because the Combined Clinic attracts the able graduate student and stimulates inquiry, it is here that research, both clinical and laboratory, naturally develops. As an example of this I would call attention to the fact that it was the unexplained splenomegalies that stimulated this clinic to study experimentally portal bed obstruction and portal bed irritation. Experiments in schistosomiasis in monkeys in Puerto Rico, and in the portal areas of liver and spleen in other species in our surgical laboratory, are at present being studied and will be reported in subsequent communications from this clinic.

630 West One Hundred and Sixty-Eighth Street.

## HEMOLYTIC JAUNDICE

ITS DIAGNOSIS, BEHAVIOR AND TREATMENT: A  
REVIEW OF FORTY-FIVE CASES

WILLIAM P. THOMPSON, M.D.  
NEW YORK

The problem of the accurate diagnosis and subsequent treatment of patients presenting evidence of increased blood destruction with splenomegaly has long been of importance in medical and surgical clinics. Various criteria have been suggested for differentiating the various types of disturbances producing this syndrome, but considerable confusion still exists.

With the hope of obtaining a clearer understanding of the nature of this syndrome, the Spleen Clinic has been conducting a special study during the past six years. This study has resulted in a definite change in our point of view concerning diagnosis, indications for treatment and the therapeutic results that may be expected. Although much of that which follows has been said before, a difference in emphasis will be apparent.

During the past six years the Spleen Clinic has been able to study a total of forty-five patients presenting the clinical picture known as hemolytic jaundice. These cases have all been followed at regular intervals by this combined medical-surgical group; frequent laboratory tests have been made by technicians directly responsible to this clinic; separate records of each patient have been kept in our own files, as well as in the hospital record room; individual patients have been pursued, when pursuit was indicated, by our own social service worker, and nearly all splenectomies have been performed by our chief of clinic, Dr. Allen O. Whipple. With this method of study it has been possible to collect an enormous amount of data over extended periods of time with a degree of accuracy and uniformity difficult to obtain otherwise.

The term hemolytic jaundice has been used as a general diagnosis to include all patients presenting increased hemolysis of red cells within the body coincident with evidence of regeneration. In practice this definition is associated with variable jaundice and splenomegaly.

The Spleen Clinic, after many attempts to classify further the diseases causing this syndrome, has finally thought it wise to accept only two subdivisions. The first of these is a uniform, recognizable, curable entity: typical hemolytic jaundice. The second subdivision consists of a heterogeneous variety of disturbances grouped together under an intentionally vague term—the atypical hemolytic anemias.

### TYPICAL HEMOLYTIC JAUNDICE

Typical hemolytic jaundice is, in our experience, a uniform and readily recognizable disease entity, provided certain diagnostic criteria are rigidly maintained. It is a chronic disease of long duration and of relative mildness. Acute exacerbations may occur, but these acute episodes are not common. The presenting symptom is chronic, variable jaundice and the outstanding physical finding is splenomegaly. A positive diagnosis is made in the laboratory. In all cases of typical hemolytic jaundice the peripheral blood contains the

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Spleen Clinic of the Presbyterian Hospital.

spherical microcytes that we believe are as pathognomonic of this disease as are the sickle cells in sickle cell anemia.

We in the Spleen Clinic have had the opportunity of studying thirty cases of this typical disease; of these thirty patients, eighteen have had their spleens removed. The more important clinical and laboratory data are presented in tables 1 and 2.

#### THE ATYPICAL HEMOLYTIC ANEMIAS

In marked contrast to typical hemolytic jaundice is our experience with the atypical hemolytic anemias. In the former group a definite diagnosis is promptly available, knowledge of the disease mechanism is accumulating, and the results of splenectomy can be predicted with security.

The atypical group comprises a total of fifteen cases presenting subacute or chronic acholuric jaundice, anemia with evidence of regeneration and splenomegaly. In all fifteen the possibility of typical hemolytic jaundice was considered, and in all fifteen this diagnosis could not be sustained because the blood failed to show the spherical microcytes with their attendant fragility changes.

In addition, the clinical behavior of this group, while under observation, showed differences from the typical cases, the behavior depending on the type of disturbance responsible for the hemolytic anemia.

Of the fifteen patients, three died with reticulum cell sarcomas of the spleen. These three patients were elderly and the disease progressed relentlessly to a fatal termination. Biopsy of affected superficial lymph nodes revealed the correct diagnosis in one. In the other two a diagnosis of atypical hemolytic anemia was all that could be sustained until autopsy revealed the neoplastic process. This type of hemolytic response to this type of neoplasm has been reported.<sup>1</sup>

Of the fifteen, two patients presented the syndrome of chronic hemolytic anemia in association with a fully positive Wassermann reaction. Treatment of their syphilis was followed by a cessation of the increased hemolytic activity, a regression in the size of the spleen and the amelioration of symptoms. Although hemolytic jaundice due to syphilis has been described, there is no available knowledge whatever concerning the mechanism.

Of the fifteen, one died of extensive caseating tuberculosis of the spleen and lymph nodes. Again the mechanism is not understood.

Of the fifteen, five are being followed at the present time. All five have chronic hemolytic anemia with jaundice, the etiology of which is quite unknown.

Splenectomy was performed in the remaining four. In two, operation resulted in no change in the activity of the hemolytic process. In the other two the hemolytic process progressed and the patients died and came to autopsy. There is nothing uniform in these four cases, they bear no resemblance to one another or to any other cases, and their diagnoses remain entirely obscure.

Details of eleven of this group appear in table 3.

In summary form, our clinical experience with this group of forty-five cases has led to the following tenets:

1. The syndrome of chronic variable acholuric jaundice, chronic variable anemia with regeneration and moderate to marked splenic enlargement, indicates the presence of a hemolytic process within the body.

2. Cases presenting this syndrome may be divided into two major groups:

- (a) Typical hemolytic jaundice.

- (b) The atypical hemolytic anemias.

3. The first symptoms of either group may have their onset at any age and in any race. There is no appreciable sex difference in the incidence.

4. Although a familial background of a similar process is somewhat more common in the typical hemolytic jaundice group, this family history may be present or absent in either group without affecting the diagnosis in any way. The former subdivision of cases into congenital and acquired types is therefore no longer valid.

5. Typical hemolytic jaundice is a clear cut definite disease entity, the diagnosis of which depends on the finding of spherical microcytes, with their attendant fragility changes, in the peripheral blood. Once the active phase of this disease is established it will continue, with fluctuations in intensity, until splenectomy is performed. The splenic pathologic changes are uniform and characteristic. Splenectomy results in an immediate cessation of the increased hemolytic activity with a prompt return of the blood values to normal. These brilliant results have been observed in all cases and persist without exception for as long as sixteen years after splenectomy.

6. The atypical hemolytic anemias comprise a heterogeneous group of disturbances that are associated with increased blood destruction and splenic enlargement. In some of our cases the primary disturbance has been neoplastic, in others infectious, in many unknown. Splenectomy is not indicated, for obvious reasons, in this group.

7. Correct clinical diagnosis before operation is therefore essential.

#### THE NATURE OF TYPICAL HEMOLYTIC JAUNDICE

The clinical study of patients with typical hemolytic jaundice before, during and after operation has led to certain conclusions concerning its behavior. Examination of the accompanying tables will show that there is no uniformity as to sex or racial distribution. The symptoms of chronic anemia with jaundice may appear at any age or an enlarged spleen may be found in an individual being examined for some unrelated complaint. The anemia may be mild or severe, or, in the latent cases, the blood count may be quite normal. The degree of jaundice varies likewise but is always proportional to the degree of anemia. The percentage of reticulocytes also varies within wide limits, depending, again, on the severity of the hemolytic process.

Although so many of the symptoms and signs of this disease appear to be variable, certain other features are uniform and constant. By observing the latter group of changes and by trying to understand their significance we have slowly come to a feeling of relative diagnostic security and confidence. In addition, these studies have helped materially in our understanding of the nature of this disease and how it works.

In every case of typical hemolytic jaundice the peripheral blood smear contains erythrocytes the diameter of which is obviously much less than normal but which in addition show no central pallor. In wet preparations these small cells appear spherical. With the micromanipulator these cells can be slowly and carefully examined and their spherical shape confirmed.

It is important that these cells should be detected and counted in wet film preparations with, when possible, the aid of the micromanipulator. Techniques that give

1. Howard, Tasker: J. Lab. & Clin. Med. 14: 1157 (Sept.) 1929.

the mean corpuscular volume may be misleading, as these spherical cells form only a small proportion of the total red cell colony, and many of the remaining cells, the reticulocytes, may be considerably larger than normal. In the presence of a high degree of reticulocytosis, mean corpuscular volume readings may be on the high side of normal and the spherical cells remain undetected.

The presence of these spherical cells in the blood of patients with typical hemolytic jaundice has been "discovered" by many observers, including myself. To Naegeli, however, belongs the credit for their original description; he suggested the possibility that these cells were responsible for the altered fragility to hypotonic salt solutions, which is such a constant finding. The work of Vallery-Radot on the relation between red cell

diameter and fragility to hypotonic salt is of sufficient interest to warrant the presentation again of his table (table 4).

It was not until the recent work of Haden<sup>2</sup> appeared, however, that this relationship between shape, size and hemolysis was conclusively proved. His work leaves no doubt about the fact that these spherical cells are alone responsible for the fragility changes seen in all cases of typical hemolytic jaundice.

In addition, evidence is available to suggest a serious consideration of the importance of these spherical cells in the production of the active disease process.

This chain of evidence, although fragmentary in places, can be presented in order:

1. The fact can be accepted that all patients with typical hemolytic jaundice, as well as their relatives

ary 1933. The patient recovered promptly and has been entirely well since operation. Sections of the spleen are typical of hemolytic jaundice.<sup>3</sup>

At operation the following data were obtained: spherical microcytes in splenic arterial blood, 10.4 per cent; spherical microcytes in splenic vein blood, 8.4 per cent; spherical microcytes in splenic pulp, 48.0 per cent.

A small fragment of spleen is washed carefully in warm physiologic solution of sodium chloride to remove the excess blood. The fragment is then ground in a watch glass with a few drops of the patient's serum, smears are made and the proportion of spherical cells are counted.

4. There is enough evidence, I believe, to warrant the assumption that all the increased red blood cell destruction that results in the active phase of the dis-

with the latent disease, have these spherical microcytes circulating in the peripheral blood. These abnormal cells constitute from 10 to 25 per cent of the total number of erythrocytes, the remaining cells being either reticulocytes or normal red blood cells. We have never observed reticulation in the spherical cells.

2. These spherical cells are directly responsible for the fragility changes to hypotonic salt solution.<sup>2</sup>

3. These spherical cells appear to be selectively removed from the general circulation by the spleen, where they are found in larger numbers than in the peripheral blood.

Sample Observation: A. H., an American woman, aged 28, with chronic anemia and jaundice, had a red blood cell count of 2,500,000; hemoglobin 52 per cent, reticulocytes 33 per cent, and fragility beginning at 0.625 per cent of sodium chloride. The spleen was moderately enlarged. There were no gallstones. Splenectomy was performed by Dr. Whipple in Febru-

ary 1933. The patient recovered promptly and has been entirely well since operation. Sections of the spleen are typical of hemolytic jaundice.

At operation the following data were obtained: spherical microcytes in splenic arterial blood, 10.4 per cent; spherical microcytes in splenic vein blood, 8.4 per cent; spherical microcytes in splenic pulp, 48.0 per cent.

A small fragment of spleen is washed carefully in warm physiologic solution of sodium chloride to remove the excess blood. The fragment is then ground in a watch glass with a few drops of the patient's serum, smears are made and the proportion of spherical cells are counted.

of splenectomy. Our therapeutic results in the eighteen cases in which splenectomy was performed are uniform and coincide with the results of others. Removal of the spleen is immediately followed by cessation of the increased hemolytic activity. Relief is immediate and, apparently, permanent.

A study of the factors that might be influenced by splenectomy results in the acceptance of only one; the excessive hemolysis stops. I can see no reason to consider any other influence, as the cessation of excessive hemolysis will explain all the changes observed.

With the removal of the site of increased destruction of erythrocytes, the serum bilirubin and the urobilin excretion figures drop promptly to normal levels. The already overactive bone marrow rapidly raises the erythrocyte concentration in the peripheral blood. As the red blood cell count rises, the stimulus for new erythrocytes falls and the proportion of reticulocytes drops. All these changes toward normal appear within a few hours after operation and are concluded in from two to three weeks. We have yet to observe any changes suggesting subsequent increase above normal in erythrocyte destruction. The results of operating appear to be permanent.

The only other theoretically possible effect of splenectomy would be some change in the spherical cells and their fragility. That some such change does occur has been suggested at various times by various authors. Their conclusions are, as a rule, variable, and the changes usually observed are slight shifts in the fragility test.

Our observations warrant the definite conclusions, in the postsplenectomy cases, that the spherical cells persist with their attendant fragility changes for as long after splenectomy as time has permitted observation. The proportion of these typical cells may vary within relatively narrow limits, but they have been demonstrated in patients sixteen years after operation in concentrations as high as 14 per cent.

The recent report of Lord Dawson of Penn<sup>5</sup> of typical fragility changes persisting forty-five years after splenectomy leaves little doubt that the spherical cells are not affected by this surgical procedure.

TABLE 4.—Relation of Red Cell Diameter and Fragility to Hypotonic Salt (Vallery-Radot)

What may be termed the life-history of this disease can best be presented by a brief review of the records of two of our patients:

These patients are half sisters. Their father, for many years before his death, suffered from chronic anemia and jaundice, as did the grandfather. A diagnosis of hemolytic jaundice was never made but it seems more than likely that they had this disease.

Our two patients had a normal, healthy childhood. In 1898 both became chronically ill with a sallow color and anemia. Many physicians were consulted, various diagnoses were offered, a multitude of medicinal preparations was prescribed and taken but the chronic anemia and jaundice continued.

5. Dawson, B. E.: Brit. M. J. 2: 699 (Oct. 15) 1932.

In 1920, after twenty-two years of this chronic intermittent disorder, the younger sister came to the Presbyterian Hospital because of a recent attack of colic in the right upper quadrant. A diagnosis of cholelithiasis was made and operation advised. April 10 a gallbladder containing stones was removed. At the same time the spleen was taken out. Convalescence was stormy but the patient survived. Histologic study on sections of the spleen is recorded as being compatible with hemolytic jaundice—the patient's clinical diagnosis is recorded at the time she left the hospital as chronic cholelithiasis and splenic anemia. She then disappeared from medical observation, the disappearance being due not only to the fact that no further attacks of colic were experienced but also because the chronic jaundice vanished.

".....	Very faint trace	3.6 mg. per 100 cc.

Fifteen years later we were reviewing the sections of spleen collected by the Department of Surgical Pathology. Although the sections were old and faded, one glance at the spleen of this patient warranted the diagnosis of typical hemolytic jaundice. The patient and her sister were pursued and their clinical pictures brought up to date.

There is no question that both these patients have typical hemolytic jaundice. Spherical microcytes are present in the peripheral blood of both, and the response of their blood to hypotonic salt solutions is similar and typical. In one, splenectomy resulted in a cessation of excessive erythrocyte destruction. In the other this excessive destruction with its attendant jaundice and anemia continues now into its thirty-eighth consecutive year. Their respective blood studies at the present time are given in table 5.

It would seem that there was little doubt but that these two patients inherited the spherical microcytes from their father. The hemolytic jaundice became active in the two at approximately the same time and continued in one until splenectomy twenty-two years later and in the other to the present time, thirty-eight years after the onset.

The blood of the two patients contains spherical microcytes in approximately the same proportions. As far as one can see, the only difference between these two patients is the spleen. In one the active phase of the disease ceased with splenectomy sixteen years ago; in the other the active phase continues.

This evidence, I feel, warrants the conclusions that, given the inherited spherical microcytes and increased hemolytic activity, one has the disease known as typical hemolytic jaundice and that this disease, once active, remains active until the site of increased hemolytic activity is removed.

Three important unsolved questions remain:

1. Little or nothing is known about the genetics of transmission of these spherical cells.
2. Little or nothing is known about the factors that initiate the excessive hemolysis which signals the onset of the active disease. It is known that individuals exist, as members of hemolytic jaundice families, whose blood contains these spherical cells and in whom increased hemolysis is not taking place. We also know that these latent cases may become active at any time in their career from, in our series, the age of 6 weeks to the age of 58 years. We also know that, when the disease once becomes active, spontaneous remission will not occur and that chronic anemia with jaundice will

persist until splenectomy. But we have not been able to associate the change from latency to activity with any as yet discernible event. Occasionally an acute infection precedes the onset of jaundice; in the majority of cases no such history can be elicited.

3. We do not know whether a normal spleen interposed in a circulation containing spherical erythrocytes would behave as and assume the histologic characteristics of a spleen presenting hemolytic jaundice.

#### CONCLUSIONS

1. Hemolytic anemia with jaundice and splenomegaly has been observed in forty-five patients.

2. This syndrome may be separated into two groups:

(a) Typical hemolytic jaundice.

(b) Atypical hemolytic anemia.

3. Typical hemolytic jaundice is a clear cut definite disease entity the course of which can be predicted and the mechanism of which is beginning to be understood.

4. The atypical hemolytic anemias comprise a heterogeneous group of conditions in which there is increased red cell destruction.

5. The symptoms of typical hemolytic jaundice are promptly, completely and permanently relieved by splenectomy. The atypical hemolytic anemias have not been benefited by this procedure.

6. Accurate preoperative diagnosis is of great importance.

## THE RESULTS OF SPLENECTOMY IN THROMBOCYTOPENIC PURPURA

A COMPARATIVE STUDY OF TEN CASES IN  
WHICH SPLENECTOMY WAS PERFORMED  
AND ELEVEN CASES TREATED BY  
CONSERVATIVE METHODS

DANIEL N. BROWN, M.D.

AND

R. H. EGERTON ELLIOTT, M.D.

NEW YORK

Two centuries have elapsed since Werlhof originally described a case of purpura haemorrhagica, but the advances made in our knowledge of the disease have all occurred in the past fifty years. Its clinical manifestations remain as he so vividly described them, though little is known, even today, about the mechanism of their production. Its characteristic blood picture has become familiar. It is well known that many cases are closely associated with the factor of infection, that some are caused by toxic agents and that others occur in the course of diseases affecting the hematopoietic and reticulo-endothelial systems. Some of these cases can be treated effectively. There is, however, a group of cases in which the etiology remains entirely obscure. Strangely enough, it is this group that can be treated with the greatest assurance of success.

For many centuries, physicians have recognized the existence of hemorrhagic diseases. It was not until 200 years ago, however, that purpura haemorrhagica emerged from this group as a clinical entity. The disease was first described in 1735 by one of the greatest physicians of the eighteenth century, Paul Gottlieb

Werlhof.<sup>1</sup> During the following century and a half no important contribution was made to the knowledge of the disease, and it remained in comparative obscurity. In 1887 an observation of great importance was made by Denys,<sup>2</sup> a Belgian histologist. He pointed out an almost complete absence of platelets in blood smears of some patients with purpura. Two years later Hayem<sup>3</sup> called attention to this finding and in 1891<sup>4</sup> reported two cases of purpura presenting low platelets and poor clot retractility—the latter being an observation which was apparently original with him. Four years later he<sup>5</sup> wrote "The two constant and pathognomonic characteristics are the rarity of hematoblasts and the absence of transudation of serum after the coagulation of the blood" (*les deux caractères constants et pathognomoniques sont donc la rareté des hématoblastes et l'absence de transudation du sérum après la coagulation du sang*). In 1909 Pagniez<sup>6</sup> demonstrated a connection between clot retraction and the number of platelets, and in the following year Duke<sup>7</sup> described the method still in use for the estimation of bleeding time and reported two cases of purpura in which the bleeding time was prolonged. The next landmark in the history of the disease came in 1916 when, at Kaznelson's suggestion,<sup>8</sup> Professor Schloffer of Prague performed the first splenectomy in a case of purpura haemorrhagica. The dramatic results of this operation were reported in the same year by Kaznelson.<sup>9</sup> This report stimulated renewed interest in purpura and much has been written on the subject since. The results of splenectomy have received considerable attention and the operation, though still resting on an empirical basis, has become firmly entrenched as the most effective form of therapy in certain cases.

Since Kaznelson's paper in 1916, many excellent reports on the results of splenectomy in thrombocytopenic purpura have come from European and American clinics. In 1926 Whipple<sup>10</sup> reviewed eighty-one cases, including three of his own. The operative mortality in this group was 16 per cent. Two years later Spence<sup>11</sup> was able to add twenty-three more cases,<sup>12</sup> bringing the total number of reports published in the two groups to 104. In the following year Quénu<sup>13</sup> collected a number of additional cases and found an operative mortality of 16 per cent for the entire series of 122 cases. In 1932 Eliason<sup>14</sup> summarized the situation to date, giving

From the Department of Surgery, Columbia University College of Physicians and Surgeons, and the Spleen Clinic of the Presbyterian Hospital.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL by the omission of a number of case reports. The complete article appears in the authors' reprints.

figures on 213 collected cases, five of which were his own. The results of splenectomy in this group were excellent. Cures were reported in 73 per cent and improvement in an additional 8 per cent; i. e., 81 per cent of the patients were benefited by the operation. The operative mortality was 13 per cent for the entire group but only 7 per cent in the 113 cases reported between 1928 and 1932. Of the 156 cases reported as cured, only five had been followed for five or more years. In the same year Giffin<sup>15</sup> published the results in forty-four cases in which splenectomy was done at the Mayo Clinic. The operative mortality was 7 per cent. However, twenty splenectomies were performed for purpura between March 7, 1923, and Jan. 1, 1927, without a single operative mortality. One patient died of a recurrence of the disease five years after operation. The remaining nineteen patients were alive and had suffered no serious hemorrhagic manifestations in a follow-up period of from five to nine years. In 1934 Pemberton<sup>16</sup> reported thirteen more cases from the Mayo Clinic, bringing their total to fifty-seven cases, the largest series so far published from any single clinic. Four patients died while still in the hospital, giving a figure for operative mortality of 7 per cent for the whole group, or the same as that quoted by Giffin for their first forty-four cases. Permanent remission of the disease was achieved in 63 per cent of the patients who survived; an additional 35 per cent were improved, and in only one case did the disease recur in acute form.

Ever since the introduction of splenectomy in the treatment of thrombocytopenic purpura, surgeons have attempted to divide the disease into acute and chronic types. This has resulted in considerable confusion, as many of them have not defined the terms "acute" and "chronic." It is apparent that some surgeons include all fulminating cases in their acute group, regardless of the duration of the disease, thus including chronic cases in acute exacerbations. This has naturally led to inaccuracies in the results published for both groups. Nevertheless, it is only fair to point out that, if anything, this would tend to decrease the mortality for the chronic group without materially affecting the mortality for the acute group.

Until comparatively recently it was felt by most surgeons that splenectomy was definitely contraindicated in acute cases. Whipple (1926) reported seven deaths in eight cases of acute purpura, and Spence (1928) found ten deaths in twelve cases. Eliason (1932) gave an operative mortality of 34.3 per cent for the thirty-five acute cases in his series, but called attention to a drop to 13.6 per cent in the twenty-two splenectomized between 1928 and 1932. At present the available figures indicate an operative mortality of about 7 per cent for all cases of thrombocytopenic purpura, that for the acute cases being in the vicinity of from 13 to 14 per cent and for the chronic cases from 5 to 6 per cent.

It is apparent from these figures that factors have come into play in recent years which have strikingly reduced the mortality from splenectomy. These factors are probably:

1. More accurate diagnosis.
2. Better preoperative preparation of the patient.
3. Advances in surgical technic and a more careful choice of the anesthetic.

15. Giffin, H. Z.: Problems Associated with the Treatment of Essential Thrombocytopenic Purpura: Notes on Forty-Four Cases in Which Splenectomy Was Performed, *Tr. A. M. Physicians* 47: 218-227, 1932.  
16. Pemberton, J. deJ.: The Diagnosis and Treatment of Purpura Haemorrhagica, *Am. J. Surg.* 24: 793-806 (June) 1934.

The operative mortality will probably always be higher in fulminating cases, irrespective of the duration of the disease, since the patients are in a more serious condition when they come to operation. It also seems likely that it will always be higher in the incipient group, as correct diagnosis is often impossible in these cases, the purpura and thrombocytopenia frequently being merely manifestations of some underlying disease which only subsequent events will reveal in its true colors. It is, however, no longer so high that it can be considered a contraindication to a measure which, when performed by an experienced surgeon in selected cases carefully prepared for operation, may be the means of saving life.

#### MATERIAL

It is our purpose in this paper to present twenty-one cases of so-called idiopathic thrombocytopenic purpura studied in this clinic in the past sixteen years.<sup>17</sup> This group includes all cases adequately enough worked up and sufficiently followed to establish the diagnosis beyond reasonable question. In ten of these patients splenectomy has been done. They have been followed for an average period of five and one-half years, (five of them for over six years)—the longest follow up being eleven years and the shortest eleven months. The eleven nonsurgical cases are presented as a control group. They have been followed for an average period of four years (six of them for over three and a half years)—the longest follow up being eleven years and the shortest one month. We have appended the reports of two cases not included in this group to illustrate the criteria used in the selection of cases.

#### REPORT OF CASES

CASE 1.—History.—A. V. V., an American born schoolboy, aged 12 years, was admitted to the hospital in July 1920 for purpura of the skin, epistaxis and bleeding gums of four days' duration. The family history showed no "bleeders." The past history was essentially negative. The diet was adequate in every respect. On physical examination the boy was healthy looking, with skin speckled with fine purpuric spots and ecchymotic areas. The eyes and ears were normal. The nose contained dry crusts of blood. The condition of the teeth was fair; the gums were oozing. The tonsils were large and cryptic but apparently not infected. There were moderately enlarged lymph glands in both axillae but nowhere else. The spleen was not palpable, and there were no other significant changes.

Laboratory Examination.—Examination of the blood revealed: red blood cells 3,200,000; hemoglobin not recorded; white blood cells 12,200 with a normal differential count, bleeding time 5 minutes, clotting time 25 minutes, clot retraction prolonged, platelets not counted. The urine showed many red blood cells; a stool guaiac test for occult blood was strongly positive.

Course.—About one week after admission the patient was given a transfusion of 350 cc. of citrated blood. Following this he seemed definitely better and all bleeding stopped; red blood cells rose to 4,100,000 with a hemoglobin of 84 per cent (Sahli), bleeding time dropped to 2 minutes, clotting time to 6 minutes, the clot retracted normally and no more blood was found in the urine or stool. The patient was discharged after two weeks in the hospital and for the next eight months was followed closely in the clinic. A month after discharge, mild purpuric symptoms recurred and persisted for a short time. He then passed through a period of several months when he was free from all bleeding but in March 1921 had to be readmitted with a fairly severe recurrence.

On this admission the physical examination was essentially as reported previously, except that his teeth had been cleaned up and were in excellent condition. The red and white cell counts and the hemoglobin were all within normal limits; the platelets were 20,000. He was tried out on an emulsion of turpentine

17. Because of lack of space this paper is abbreviated in THE JOURNAL by the inclusion of reports of only six cases. The entire series will be found in the authors' reprints.

and acacia (10 minims [0.6 cc.] three times a day) and also received four transfusions, to which he was slow in responding. After two months he was discharged with all bleeding stopped, but the platelets numbered only 5,000. For the next three and one-half years his course, as followed in the outpatient department, was relatively benign and, though the platelet count never rose over 95,000, he remained practically free from bleeding. In October 1924, however, he again had an acute flare up requiring admission.

On this occasion the platelets numbered 20,000, bleeding time  $31\frac{1}{2}$  minutes, clotting time 7 minutes. He remained in the hospital eight weeks and showed slow but steady improvement. After leaving the hospital he failed to maintain his improvement and was readmitted for splenectomy three weeks after discharge. At this time, however, his bleeding was minimal; the platelets were too few to count accurately. Operation was performed by Dr. Allen O. Whipple on December 27, being preceded by a transfusion of whole blood. The postoperative course was uneventful. Platelets rose abruptly on the third day after operation to 180,000; bleeding time dropped to 2 minutes and all gross bleeding ceased. The platelet rise, however, was not maintained; and, though the patient had no further symptoms save an occasional purpuric spot on the skin, the count on discharge, three weeks later, had dropped back to 10,000.

For a time it seemed as though the disease had been permanently arrested, for the patient was free from all bleeding for the next eight months. Toward the end of the first year after operation, however, he had two colds and broke out with mild bleeding manifestations with each. The platelet count never went above 80,000, and eighteen months after splenectomy he was admitted for the fifth time in a fulminating flare up of the disease. Despite two transfusions and the administration of blood-coagulants, he died of a cerebral hemorrhage four days after admission. Permission for a postmortem examination, unfortunately, could not be obtained.

**Summary.**—A case of severe chronic thrombocytopenic purpura in an adolescent boy was followed through its entire duration of six years. Splenectomy was performed during a relatively quiescent phase of the disease without material benefit. The most outstanding characteristic of the case was its susceptibility to severe exacerbations, of which there were four, the last ending fatally.

**CASE 5.—History.**—M. M., a Russian-Jewish schoolboy, aged 13 years, first admitted to this hospital in August 1928, gave an eight year history of frequent epistaxis and easy bruising. There were no "bleeders" in his family and the past history was essentially negative. On physical examination he appeared chronically ill but aside from petechiae, ecchymosis, a spleen that was felt with difficulty, and a positive tourniquet test there were no other significant physical changes. A laboratory work up showed: hemoglobin 65 per cent; red blood cells 3,700,000; white blood cells 8,700, with a normal differential count; platelets 6,000; bleeding time 10 minutes; clotting time 3 minutes; clot retraction poor; urine negative for red blood cells; stool guaiac test strongly positive. After a thorough search for foci of infection had been made with negative results it was decided that he had "idiopathic" thrombocytopenic purpura and that the spleen should be removed.

**Course.**—August 20 a splenectomy, followed by transfusion, was performed by Dr. F. B. St. John. Following operation his course was very smooth and he had a splendid platelet rise. On the third postoperative day the platelets were 210,000 and on the ninth postoperative day they were 360,000. By his sixteenth day the bleeding time had fallen to  $1\frac{1}{2}$  minutes and since then the platelets have never been below 175,000 nor his bleeding time above the figure just given. Interestingly enough, though the bleeding time has always been within normal limits, the clot retraction has remained prolonged. He is recorded to have had a slight epistaxis about six weeks after splenectomy and another twenty months later, but there have been no other episodes of bleeding. A noteworthy feature of this case was the patient's leukocyte response to what appears to have been an acute pharyngitis and tonsillitis, which occurred three weeks after operation. This response consisted of a marked lymphocytosis, reaching as high as 81 per cent in a total white cell count of 21,000. A relative lymphocytosis was reported as late as May 1930, but there has been no reason to believe that the patient has a lymphatic leukemia. He was last seen in the Splen Clinic in February 1936 and at that time was in perfect

health with no clinical evidence or history of bleeding. The blood values were all well within normal limits, with the exception of the clot retraction, which was still prolonged; the capillary resistance, as measured by the Dalldorf apparatus, was 40.

**Summary.**—In a case of moderately severe chronic thrombocytopenic purpura a seven and one-half year follow up has revealed no convincing evidence of a recurrence of the disease following splenectomy—a dramatic result thus far.

**CASE 9.—History.**—G. S., an American-born schoolgirl, aged 15, admitted to the hospital in April 1933, complained of easy bruising and profuse epistaxis for the previous seven years and vaginal bleeding for the previous six months. Her mother had pernicious anemia, which was being controlled with liver therapy. The patient had always eaten a well balanced diet. She was said to have had rheumatic fever and chorea eight years previously. The bleeding tendency had started following a tonsillectomy and had subsequently become sufficiently severe to require five admissions to another hospital. All efforts at conservative therapy (including repeated transfusions and a course of x-ray treatments to the spleen) had failed to alter the course of the disease more than temporarily. On physical examination the patient was markedly exsanguinated with extreme pallor, rapid, thready pulse and cold extremities. The skin was clear. The eyes, ears, nose and throat were all normal. The teeth were all excellent. The spleen was not palpable. There was profuse bleeding from the vagina. The remainder of the examination was not noteworthy.

**Blood Studies.**—Hemoglobin was 32 per cent, red blood cells 2,200,000, white blood cells 5,700, with a normal differential count, platelets 15,000, bleeding time 4 minutes, clotting time  $5\frac{1}{2}$  minutes and clot retraction not reported.

**Course.**—Immediate operation was deemed advisable and the patient's spleen was removed by Dr. Allen O. Whipple on the day following admission. During the operative procedure the patient had a sudden, very profuse epistaxis which made it seem doubtful at the time whether she would leave the operating table alive. Her condition, however, was improved markedly by transfusion and other supportive measures and by the second postoperative day the platelets had risen to 356,000. On the third day after operation all bleeding ceased, and on the sixth day the platelets spiked to a high of 1,025,000, but during the next ten days they dropped back to 111,000. She left the hospital three weeks after operation, having had a smooth postoperative course, and on discharge the hemoglobin was 70 per cent, red blood cells 4,100,000, platelets 134,000. During her subsequent follow up she has had no recurrence of purpuric manifestations and the platelets have remained at or above 129,000. She has recently had two nosebleeds, however, which, in the opinion of a consulting otolaryngologist, are a purely local phenomenon and are not connected with the patient's general condition. The most recent bleeding time was  $2\frac{1}{2}$  minutes.

**Summary.**—In a case of severe chronic thrombocytopenic purpura, splenectomy was performed as a life-saving measure during an exsanguinating exacerbation of the bleeding tendency. As far as one can judge from a two and one-half year follow up, the disease is cured.

**CASE 13.—History.**—R. V., a Russian-Jewish housewife, aged 40, admitted to the hospital May 5, 1921, complained of bleeding from the vagina, nose and gums and into the skin for the previous three months. There were no bleeders in the family. The patient had always been healthy until the onset of her illness. Her periods had been regular and not excessive until three months prior to admission, when she began to have menorrhagia. Her last period had started eighteen days previous to entering the hospital and she was still bleeding profusely on admission. On examination the patient was obviously anemic and very weak. Scattered over the trunk and extremities were many old and new purpuric spots of various sizes. Two retinal hemorrhages were present in the left eye. The ears and throat were normal. The nose contained several crusts of dried blood. The teeth were in poor condition and the gums were oozing freely. The spleen was not felt. The patient was bleeding profusely from the vagina. There were no other abnormal changes.

**Laboratory Examination.**—Hemoglobin was 28 per cent (Sahli), red blood cells, 2,700,000, white blood cells, 17,500 with

polymorphonuclears 79 per cent, platelets too few to count, bleeding time 36 minutes, clotting time 5 minutes. The urine contained many red blood cells; stool guaiac test was negative.

*Course.*—The patient was given an immediate transfusion of citrated blood and the vagina was packed tightly. For the first month she continued to bleed profusely from the uterus despite packing and eight transfusions. Her teeth were attended to, and various forms of therapy were tried, such as intracutaneous injections of old tuberculin and oral administrations of turpentine, but the bleeding, particularly from the vagina, continued unabated. Finally, radium was applied to the interior of the uterus to produce an artificial menopause, and shortly thereafter all vaginal hemorrhage stopped. The patient received two more transfusions, making ten in all, but within a short period of time many bilateral retinal hemorrhages developed, producing partial blindness. Toward the end of the second month, however, the bleeding manifestations became milder and the platelet count finally rose to 30,000. She was discharged three and one-half months after admission, apparently free from bleeding, with normal red and white counts, normal hemoglobin and a platelet count of about 70,000. Unfortunately the patient returned immediately to her home in Texas. In 1932 (eleven years later) she reported by letter that she had completely recovered her vision and that she had been in perfect health since leaving the hospital, except for occasional purpuric spots on the skin.

*Summary.*—A case of severe incipient thrombocytopenic purpura in a middle aged woman, characterized at the onset by intractable uterine bleeding, was apparently controlled by radium sterilization. The disease has since become mild and chronic. The total follow up has been eleven years.

*CASE 15.—History.*—M. G., an Irish-American schoolgirl, aged 11 years, admitted to the hospital March 10, 1929, complained of a brown skin rash and bleeding from the mouth and nose of three weeks' duration. The mother and a paternal aunt bruised easily; otherwise there was no history of bleeding in the family. Tonsillectomy had been done seven years before. For the previous six months the mother had noted that the patient bruised easily. Present illness: In addition to the sudden onset of skin rash, epistaxis and bleeding gums, the child had been nauseated on several occasions within the previous three weeks, and her appetite was failing. On examination the patient was well nourished and well developed and did not appear ill. There were numerous small purpuric spots scattered over the entire body, with several large ecchymotic areas on both lower extremities. The eyes and ears were normal. The nose showed evidence of recent epistaxis. The teeth were excellent, the tonsils were out and the throat was entirely normal. The spleen was not palpable. Examination was otherwise negative except for slight enlargement of cervical lymph nodes and a positive tourniquet test.

*Laboratory Examination.*—Hemoglobin was 70 per cent, red blood cells 3,400,000, white blood cells 9,500 with a normal differential count, platelets 35,000, bleeding time  $28\frac{1}{2}$  minutes on one occasion and over an hour on another. Clotting time was 3 minutes, clot retraction was normal once and "fair" a second time. Roentgenograms of the sinuses were negative. The urine contained a few red blood cells.

*Course.*—The child was observed in the hospital for three weeks and received one small transfusion just before discharge. The platelets hovered between 35,000 and 40,000, and she continued to have mild bleeding manifestations throughout her stay. Splenectomy was considered, but her symptoms were not deemed severe enough to warrant operation, and she was discharged to the care of her local physician to be readmitted for immediate operation if the disease showed any increase in severity. Two days after discharge she began to bleed profusely from the gums and urinary tract. These symptoms persisted and three days later a slight speech difficulty was noted. The seventh day after leaving the hospital she began vomiting blood, became stuporous and was rushed back to the hospital, where she died forty minutes after admission from obvious cerebral hemorrhage. At necropsy, massive subdural, sub-arachnoid and cerebellar hemorrhages, both old and new, were found. In addition, extravasations of blood were found in the majority of the abdominal organs. There were no other significant changes.

*Summary.*—A deceptive, moderately severe incipient case of thrombocytopenic purpura occurred in an 11 year old child. The disease suddenly became fulminating and terminated fatally seven months after onset. This case illustrates how treacherous the disease can be.

*CASE 20.—History.*—B. S., a Russian-Jewish housewife, aged 51, first seen in the outpatient department Jan. 1, 1933, gave a history of intermittent bleeding into the skin and from the nose since the age of 12, and of profuse menorrhagia since the onset of the menses. She had had fairly severe postpartum hemorrhages after three deliveries. In addition, she stated that she had gone through an episode of headache, syncope and transient blindness in the left eye accompanied by hematemesis and melena one and one-half years previously. Two years prior to being seen in the clinic, splenectomy had been offered by another hospital. Operation was refused and high voltage roentgen therapy to the spleen had been substituted in its stead. The latter had resulted in a mild exacerbation of the bleeding tendency and the onset of an artificial menopause. There was no history of blood dyscrasia in the family. On examination the patient was obese, and did not appear ill. Her skin was speckled with a fine purpuric rash, and several large areas of subcutaneous ecchymosis were also noted. The ears, nose and throat were negative. The teeth were considered only "fair." The remainder of the physical examination was irrelevant. The spleen was not felt.

*Laboratory Examination.*—The blood readings were as follows: Hemoglobin 88 per cent, red blood cells 5,400,000, white blood cells 6,900, polymorphonuclears 72 per cent, platelets 8,000, bleeding time  $4\frac{1}{2}$  minutes, clotting time  $2\frac{3}{4}$  minutes, tourniquet test positive.

*Course.*—The patient refused to consider splenectomy and also refused to enter the hospital for observation and transfusion. She was followed closely in the hematology clinic for a period of about six months and was then lost sight of for a year and a half. During the latter period she had a hemorrhage into the right eye, which cleared up uneventfully. On her last visit, in February 1935, she was improved and the platelets numbered 18,000, the highest they had ever been while she was under observation in this clinic. The bleeding time on this and on one prior occasion was slightly over 10 minutes.

*Summary.*—A case of moderately severe chronic thrombocytopenic purpura of over forty years' duration was followed in this clinic for a period of twenty-four months and then lost sight of. Splenectomy was obviously indicated but repeatedly refused. Interesting features of the case were its extremely long duration and the fact that, though on at least two occasions the disease became severe enough to produce ocular and cerebral symptoms, there were no permanent residua.

The cases all belong to the group of thrombocytopenic purpuras commonly referred to as "idiopathic" or "essential."<sup>18</sup> They have been selected because in no instance was an obvious causative factor involved and in no instance did the purpura occur in the course of some other disease affecting the hematopoietic or reticulo-endothelial systems. As far as possible we have excluded all cases in which an associated infection might reasonably be considered responsible for the purpura. The exaction of such a rigid standard in the choice of material has naturally resulted in the omission of several cases that would ordinarily be considered acceptable in this group (i. e., cases 11 and 12). We believe, however, that a fairer appraisal of the results of treatment can be made when such a standard is adhered to.

In classifying our cases we have followed the outline proposed by Giffin in 1932. This divides the group into (1) chronic cases and (2) incipient cases in their primary attack, irrespective of the exact duration of the disease. The cases have been further subdivided by characterizing them as mild, moderate or severe.

18. We feel very strongly that these terms should be discarded, as it is misleading to imply the absence of a causative factor merely because one is ignorant of its nature.

## AGE AT ONSET, SEX, NATIONALITY AND RACE

Of the twenty-one cases here presented in the control and operative groups 76.2 per cent, or slightly more than three fourths, became manifest before the fourth decade. There were seven in the first decade, five in the second, four in the third, two in the fourth and three in the fifth. The disease was more than four times as prevalent among females as among males, the exact ratio of distribution between the sexes being seventeen to four. In this connection it is of interest to note that six of the seven patients in whom the onset took place during the first decade were females. This finding is noteworthy in that in their paper on purpura in childhood, McLean, Kreidel and Caffey<sup>19</sup> found that the

to the hospital or first observation in the outpatient department. Skin purpura was present in all but two cases on the first examination. Bleeding into or from the mucous membranes was present in eleven instances. Gross or microscopic hematuria was recorded in only six cases. In only one was there frank bleeding from the bowel. In four others the guaiac test of the stool was reported as positive, but in three of these it could have been due to swallowed blood. Retinal hemorrhages were noted in two cases and vitreous hemorrhage was noted in one. In eight of the twenty-one cases the spleen was recorded as palpable on the initial examination; one of these cases was incipient, the disease having been present according to the history for

males outnumbered the females by two to one. As far as the nationality is concerned, our observations are in agreement with those of other observers in that the disease showed no predilection for race or nationality: the two series embraced four Americans, one American Negress, four Italians, one Austrian, two Irish, one Irish-American, one Swedish-American, and seven of Russian-Jewish extraction. The high incidence of the last mentioned may be partially explained, we think, by the fact that the Presbyterian Hospital is located in a district in which the population is largely Jewish.

## TYPE OF DISEASE

Fifteen of the cases were chronic and six were incipient. Of the former, five were mild, seven moderately severe and three severe. Of the latter, none were mild, five were moderately severe, and one was severe.

## CLINICAL PICTURE

The clinical picture here recorded appears as it was noted by the examiner on the patient's first admission

four days; the remaining seven were chronic. Thus the spleen was palpable in one out of five incipient cases and in seven out of fifteen chronic cases.

## BLOOD PICTURE

From tables 1 and 2 it will be seen that the initial blood observations in our two groups of cases conform closely to the hematologic diagnostic criteria which have come to be associated with so-called idiopathic thrombocytopenic purpura. In none of the twenty-one cases did the platelet count exceed 45,000. The bleeding times were for the most part prolonged, and the clotting times were generally normal. The clot retraction was delayed in thirteen cases, not done in five, normal in two, and recorded as "fair" in one. The tourniquet test was reported in nine cases: in seven of these it was positive, in one faintly positive, and in one negative. The values for red blood cell count and hemoglobin varied from a low of 1,900,000 with 21 per cent hemoglobin to 5,800,000 with 100 per cent hemoglobin. In those cases in which anemia was present it was of the secondary type and varied with the duration, degree and extent of clinical bleeding. No white counts below 5,300 were recorded and the highest figure was 24,000.

19. McLean, Stafford; Kreidel, Katherine, and Caffey, John: Hemorrhagic Thrombocytopenia in Childhood: A Clinical Study of Twenty-One Cases. J. A. M. A. 98: 387-393 (Jan. 30) 1932.

In general it may be said that both the white and the differential counts were within normal values, though a polymorphonuclear leukocytosis of over 80 per cent occurred in two instances.

It will be seen that the one constant factor among the initial blood values was the thrombocytopenia. By the very nomenclature of the disease this is, of course, a primary requisite for diagnosis. With a single exception, all platelet determinations recorded in this paper were performed by a small group of permanent members of the hematology department of the hospital. All other platelet counts, including those performed by interns, were discarded as unreliable. We feel, therefore, that our platelet values are as nearly accurate as is possible in a series of this nature. Of the remaining factors included in tables 1 and 2, the same cannot be said. We do feel, however, that the blood count values (red cell, white cell, hemoglobin and differential) as

removed at operation in this series.<sup>20</sup> In only one instance (case 21) was a culture made of the spleen, and in this case a nonhemolytic streptococcus was recovered. Necropsy was not performed on the one patient who died in the operative group. Postmortem examination on the single fatal case in the control group disclosed massive subdural, subarachnoid and cerebellar hemorrhages which were both old and new; extensive extravasations of blood into the majority of the abdominal organs; a bone marrow that appeared normal except for slight hyperplasia; congestion and small areas of hemorrhage in the lymph nodes, and hemorrhage into the splenic follicles with some thickening and hyalinization of the capsule of the spleen.

#### POSTOPERATIVE COURSE

Of the ten patients who underwent splenectomy in this series, only three had postoperative courses that

TABLE 3.—Results in Cases in Which Operation Was Performed

Case	Age at Operation	Duration Before Operation	Type	Severity at Operation	Preoperative Transfusions	Post-operative Platelet Rise*	Subsequent Clinical Course	Follow Up	End Result
1	17	53 mos. intermittent	Chronic	Moderate	1	180,000 3d day	Marked improvement 1st 6 mos.; severe recurrence 18th month	18½ mos.	Died 18th month of cerebral hemorrhage
2	47	"All her life" intermittent; 3 mos. continuous	Chronic	Moderate	None	100,000 6th day	Asymptomatic past 10½ years	11 yrs.	Apparently permanently arrested
3	25	"For years" intermittent	Chronic	Mild	None	350,000 50th day	Asymptomatic except for occasional easy bruising and a questionable vaginal hemorrhage	9½ yrs.	Improved; subject to mild recurrences
4	18	10 yrs. intermittent	Chronic	Severe	3	None	Moderately severe purpura for 8½ yrs. following operation; asymptomatic since	9 yrs.	Markedly improved; excellent late result
5	13	8 yrs. intermittent	Chronic	Moderate	None	360,000 9th day	Asymptomatic since operation	7½ yrs.	Apparently permanently arrested
6	11	2 months	Idiopathic	Moderate	1	500,000 6th day	Asymptomatic except for occasional mild epistaxis	6 yrs.	Markedly improved; excellent result
7	33	10 yrs. intermittent; 3 mos. continuous	Chronic	Severe	3	None	Asymptomatic after 1st 36 mos. except for occasional black and blue spots	3½ yrs.	Markedly improved; excellent result
8	40	5 yrs. intermittent; 6 mos. continuous	Chronic	Moderate	None	\$9,000 7th day	Asymptomatic except for mild skin purpura on last follow-up visit	3 yrs.	Markedly improved; excellent result
9	15	7 yrs. intermittent; 6 mos. continuous	Chronic	Severe	1	336,000 2d day, 1,025,000 6th day	Asymptomatic since operation	2½ yrs.	Apparently permanently arrested

\* Figures represent peak of rise occurring prior to discharge.

performed by the intern staff are sufficiently accurate for the purpose of this paper. Some of the figures for bleeding time, clotting time and clot retraction, particularly the first two, are undoubtedly open to question, and it is our opinion that these determinations should be done, whenever possible, by trained technicians. Unfortunately such was not the case in the large majority of instances in our series, and this, we think, may partly explain the appearance in our tables of a clotting time which was unduly prolonged and several bleeding times which closely approach the normal.

Blood groupings were done in thirteen of the twenty-one cases. Of these eight were OI, two were AII, and three were BIII. None were in the ABIV group.

#### PATHOLOGIC CHANGES

It is generally conceded that the spleens removed in this group of thrombocytopenic purpuras are singularly free from constant pathologic characteristics and, as might have been expected, nothing of unusual interest was brought to light on examination of the ten spleens

were entirely uneventful. The complications occurring in the remaining seven cases were as interesting as they were varied. Patient 1 remained in severe shock for the first twenty-four hours after operation but thereafter had a smooth convalescence. Patient 2 did well throughout her postoperative course except for two severe nasal hemorrhages on the sixteenth and twentieth days. Patient 3 developed a bronchitis shortly after operation and on the fifth day had a massive collapse of the left lung, which in turn was followed by a wound disruption (without evisceration) on the ninth day. For the first forty-eight hours after operation, patient 6 was in marked acidosis with acetone breath and acetoneuria. Accompanying this he had a pronounced tachycardia. These complications had disappeared by the third day and did not reappear. The postoperative course in case 7 was marked by the development of a brief period of mental aberration and emotional instability. This was thought to be due either to iodoform

20. It is interesting however that, in the operative notes, enlargement of the spleen was reported in all but three cases.

poisoning from the anteoperative packing of the vagina or to cerebral hemorrhage. Shortly after operation, patient 8 developed an unexplained area of skin gangrene in the right lower quadrant. The involved skin subsequently sloughed away and the lesion was pinch grafted. Bacteriologic examination failed to reveal symbiotic or hemolytic organisms. The last patient in the operative group (case 10) developed pneumonia in the left lower lobe on the third day after operation. Resolution was delayed, considerably prolonging her subsequent convalescence.

It will be seen from the foregoing that the series of complications was long and in certain cases rather unusual. Whether or not this was pure coincidence is difficult to say. We do feel, however, that in our small series the postoperative course following splenectomy had more than the number of unexpected and unexplained complications usually seen in a series of equal size in which the operations were of a similar magnitude.

entirely asymptomatic since discharge from the hospital, though in one of the five the platelet level has remained consistently low. The discrepancy between the platelet level and the clinical bleeding illustrated in this last case has been commented on by many observers. In at least four other cases the reverse was true; i. e., mild intermittent purpura was occasionally seen throughout the subsequent follow up despite a normal or even slightly elevated platelet count.

In one case in which the platelets did not respond to operation the patient continued to have moderately severe purpura for eight and a half years and then, following pregnancy, all symptoms ceased, though the platelet count remained low. The one death reported in this series occurred eighteen months after operation from cerebral hemorrhage. It is of interest that in this case splenectomy was followed by a brief rise in the platelets to 180,000 on the third day. Subsequently a fall to below 80,000 ensued, and this figure was never exceeded thereafter. The disease was arrested for

TABLE 4.—Results in Cases in Which Operation Was Not Performed

Case	Age on Admission	Duration	Type	Severity	Transfusions	Subsequent Clinical Course	Follow Up	End Result
13	40	3 months	Incipient	Severe	10	Intermittent mild purpura for 11 yrs.	11 yrs. (by letter)	Improved
14	33	6 months	Incipient	Moderate	None	Moderately severe purpura 1st year, thereafter mild	6 yrs.	Improved
15	11	6 months intermittent, 3 weeks continuous	Incipient	Moderate	1	Severe flareup 4th week	26 days	Died of cerebral hemorrhage 26 days after admission

21	29	1½ years intermittent	Chronic	Moderate	1	Moderately severe intermittent purpura for 2 yrs.	2 yrs.	Unimproved
22	26	5 days	Incipient	Moderate	1	Asymptomatic for past 23 months	2 yrs.	Spontaneously arrested
23	51	"Since birth" intermittent	Chronic	Mild	None	Intermittent mild purpura for 1 yr.	1 yr.	Unimproved

#### BLOOD PICTURE FOLLOWING SPLENECTOMY AND SUBSEQUENT CLINICAL COURSE

In all but three of the splenectomized group there was a platelet rise following operation that reached 100,000 or better. Generally speaking the rise was initiated within forty-eight hours of operation and reached its peak within the first ten days. In one instance, however, the rise was delayed and the peak not reached until thirty days subsequent to operation. The height of the rise in all but two cases exceeded 300,000 and in one case reached 1,025,000 six days after operation. In every instance in which a rise took place it was followed by a secondary fall of varying magnitude, and in two of these seven cases the fall carried the platelets below 100,000. There were three cases in the group whose platelets remained at a low level throughout their subsequent follow up, though two of these had a temporary rise following operation. In every instance there was a varying degree of improvement in the clinical symptoms of the disease immediately following splenectomy. In five of the cases all evidence of hemorrhage ceased within seventy-two hours of operation, in at least two it ceased immediately after the procedure. Five cases have been

about eight months after operation, but the patient later died in a fulminating recurrence.

It seems appropriate to call attention here to the fact that, following splenectomy, one of our patients gave birth to a child with all the classic signs and symptoms of thrombocytopenic purpura (case 4).

*Course in Cases in Which Operation Was Not Performed* (subsequent to admission to the hospital or outpatient department).—The first of these cases was admitted to the hospital prior to the era when splenectomy became a generally accepted therapeutic measure in thrombocytopenic purpura. This patient left the hospital with the disease largely arrested, her symptoms having apparently been partially controlled by radium sterilization and ten transfusions (case 13). After discharge she moved to another part of the country but has continued to suffer with the disease, though in mild form. Case 14 yielded sufficiently to eradication of foci of infection in the teeth and x-ray sterilization so that contemplated operation seemed no longer necessary. This patient, however, still has the disease in a mild form. Case 15 was a singularly deceptive one. During the first admission to the hospital the purpura yielded so well to conservative therapy that splenectomy

was not considered necessary. Shortly after leaving the hospital, however, the patient had a fulminating exacerbation of the disease and was readmitted within a week in a moribund condition. She lived for less than one hour after admission, and necropsy revealed that death had been due to cerebral hemorrhage. In case 18 splenectomy was deferred because a leukopenia cast temporary doubt on the diagnosis. After seven transfusions the patient had improved so markedly that splenectomy was felt to be superfluous and within eight

TABLE 5.—Totals in the Two Groups

months of the onset of the disease a spontaneous arrest occurred which persisted throughout the subsequent follow up. In case 20 splenectomy was obviously the therapy of choice, but the patient repeatedly refused operation and even refused to enter the hospital for observation. The severity of her symptoms since her first visit to the outpatient department has remained essentially unchanged. In case 21 splenectomy was decided on, but the patient changed her mind and refused operation. Throughout her subsequent course no improvement in her condition has been noted.

Two cases, 16 and 23, were ambulatory and have not thus far required hospitalization despite the fact that their mild purpura continues unabated to the best of our knowledge. Of the three remaining cases, all were studied in the hospital at least once and operation was considered but rejected on account of the mildness of the symptomatology. One of the three cases remains unimproved. The other two have become spontaneously arrested. It is of interest that of the entire eleven cases in the group in which operation was not performed the platelet level has returned to a normal figure in only three instances. These three patients are the only ones in the group in which the condition has become spontaneously arrested.

## RESULTS

As will be seen from table 5, we have grouped our results for the two series under five headings: arrested, markedly improved, improved, unimproved and died. Under the first category there were four cases in the operative to three in the control group. These cases are apparently definitely arrested. In the "markedly improved" division there are four of the operative to none of the control group. These represent cases which, by reason of an occasional mild symptom or inconsistency in an otherwise perfect follow up, we cannot in conscience include among the definitely arrested. Under the heading of "improved" we have listed one splenectomized and two nonsplenectomized patients. These are individuals who still show persistent evidence of their original disease, but in a milder form. The "unimproved" category needs no explanation. It is significant, however, that there were no cases from the operative group listed under this heading, while the control series was represented by five. One case from each group was fatal. Since the single individual lost in the operative group died eighteen months after operation during an exacerbation of the disease, our operative mortality is zero.

Although we fully realize that in so small a series the validity of statistics is open to question, we have condensed the foregoing observations into the following more readily appreciated figures for purposes of comparison with other series: In the splenectomized group 80 per cent of the cases were vastly improved or arrested, while the same can be said of only 27.2 per cent of the control series. It will be seen further that under improved but by no means arrested we find 10 per cent of the operative and 18.1 per cent of the controls, and that under unimproved or died we find 10 per cent of the splenectomized and 54.5 per cent of the nonsplenectomized. In short, we have found three times as many excellent results among the operative group as among the controls, and five times as many poor results among the controls as among the operative group.

## CONCLUSIONS

1. In carefully selected cases of thrombocytopenic purpura, adequately prepared for operation, splenectomy by an experienced surgeon is a highly effective form of therapy, carrying a relatively low operative mortality.

2. The subsequent course of such patients, when compared with their lives previous to operation and with the lives of patients treated by conservative measures, justifies the risks inherent in a major operative procedure.

## THE RÔLE OF CONGESTION (PORTAL HYPERTENSION) IN SO-CALLED BANTI'S SYNDROME

A CLINICAL AND PATHOLOGIC STUDY OF THIRTY-ONE CASES WITH THE LATE RESULTS FOLLOWING SPLENECTOMY

LOUIS M. ROUSSELOT, M.D.  
NEW YORK

During the past several years in the Spleen Clinic of the Presbyterian Hospital there have been collected well studied cases of splenomegaly of all types. Many of these were readily classified in one of the several established disease entities. This presentation is an effort to abstract some order out of the large remaining number of cases that had been grouped under the inclusive caption of Banti's disease. As the study developed it became apparent, as it had to many others before us, that we were not dealing with a sequence of clinical and pathologic features as described by Banti. Instead we had an apparently heterogeneous group of cases that presented certain similar characteristics and that shall henceforth be grouped under the name of Banti's syndrome.

As a result of this investigation we shall consider the possibility of a common etiologic factor operating in all these different cases to produce a similar clinical syndrome. The following criteria, as originally laid down by Banti,<sup>1</sup> were drawn on to determine the eligi-

From the Department of Surgery, Columbia University College of Physicians and Surgeons, and the Combined Spleen Clinic of the Presbyterian and Babies hospitals.

The clinical and pathologic studies in the two cases of schistosomiasis and the experimental studies referred to in the course of this paper have been carried out at the School of Tropical Medicine under the auspices of Columbia University at San Juan, Puerto Rico. Dr. George Bachman, director, and his staff gave generous assistance in these studies.

1. Banti, Guido: Splenomegalie mit Lebercirrhose, Beitr. z. path. Anat. 24: 21, 1898; Ueber Morbus Banti, Folia haemat. 10: 33, 1910.

bility of each particular case for classification within the group. In each individual there was enlargement of the spleen, anemia of varying severity, leukopenia, often intestinal hemorrhages and sometimes ascites. The splenic lesion likewise was consistent with that described by Banti and others and will be discussed more fully in a later section.

This paper will include an outline of the essential features bearing on the diagnosis, on the indications for splenectomy and on the results following operation.

Thirty-one cases comprise the group, and in all splenectomy was performed. These patients all received detailed clinical and hematologic studies before operation and were similarly followed for long periods after operation. The follow up was done at frequent intervals and included the return of the patient for physical examination, complete blood examinations and other studies as indicated.

The thirty-one cases under consideration include all age groups from early childhood to adult life. The division as to sex was even, with sixteen females and fifteen males.

There was no suspicion of a hereditary factor in any of these cases such as one encounters in hemolytic jaundice or Gaucher's disease.

These cases represented a wide ethnologic distribution. We could find no evidence of any racial predisposition. This observation is mentioned only because of the striking racial constancy of some other forms of splenomegaly; namely, erythroblastic anemia and sickle cell anemia.

With the subsequent three exceptions, a careful inquiry into the past health of each of these patients failed to uncover any specific disease entity or other factors that might be the precursor of the splenic lesion. Two patients had the late visceral form of schistosomiasis *mansoni* with hepatosplenomegaly. In a third patient the following interesting sequence of lesions developed while he was under observation: After a severe abdominal injury a pseudocyst of the pancreas developed. This was operated on. At this time the spleen was normal in size and the blood picture was normal. Two years after this operation and three years after the injury he had a sudden severe hematemesis. On examination he was found to have a large spleen, anemia and leukopenia.

#### SYMPTOMATOLOGY

Although the disease is usually insidious in its onset, its first warnings may appear with startling suddenness. The most frequent complaint is that of a gradually developing weakness. By far the greatest number of patients in this group, sixteen in fact, declared this to be the initial symptom. Next in frequency and usually most distressing, is the gradual enlargement of the abdomen. Twelve of the group noticed this first. In two of these, distinct mention was made of feeling a lump on the left side of the abdomen. The prominent abdomen in these cases is usually the result of the splenomegaly or ascites or both these factors.

Probably the most alarming sign to the patient, and assuredly the most serious from the point of view of prognosis, is the onset of hematemesis. In eleven instances the individual was unaware of the illness until the sudden appearance of bloody vomitus. Some had only one such experience and others had it on numerous occasions. Hematemesis proved to be the first indication of the disease in six cases, while in five others

it appeared later in the course. It is interesting to analyze these cases separately. Hematemesis occurred in four of the cases of the Laënnec type of cirrhosis, in the one case of cavernomatous transformation of the portal vein, in one case of thrombosis of the splenic vein, and in four cases in which no "obstructive mechanism" was demonstrable.

Klemperer,<sup>2</sup> in reviewing the literature on the rare condition of cavernomatous transformation of the portal vein, reported twenty-three cases with nine instances in which hematemesis took place.

It is obvious that portal congestion and the development of esophageal varices do occur in the absence of liver cirrhosis and may be the result of other pathologic conditions.

The longest span over which hematemesis occurred prior to operation in this series was in a case in which it occurred twice in three years. Brahme<sup>3</sup> reported a case of splenic vein thrombosis with repeated hematemeses over a period of forty-five years.

Pain was a fairly frequent complaint and appeared in thirteen, or 42 per cent, of the group. The type, severity and location of the pain are usually dependent on the underlying pathologic lesion. Pain was present at some time in both cases of thrombosis of the splenic vein. This was severe and was located in the epigastrium or left hypochondrium and did not radiate. Besides this intense type of pain, mild epigastric, left upper quadrant and sometimes generalized abdominal pain occurred. The discomfort in some instances was apparently due to the increased weight of the spleen alone. A perisplenitis usually gave sharp pain, aggravated by deep respiration and often with an audible friction rub.

Digestive disturbances were not infrequent. Anorexia and associated weight loss occurred in six instances. Periods of nausea and vomiting were complained of by three patients. Epigastric fullness proved very distressing to three others of the group. Belching, sour eructations or diarrhea were rarely noted.

Epistaxis occurred frequently in five of the cases. There seemed to be no relation between this bleeding tendency and the platelet level. This symptom did not recur following splenectomy except in one of the cases of schistosomiasis, and this patient had only one slight nosebleed following operation. In none of these individuals was there any other hemorrhagic manifestation.

Symptoms referable to the urinary tract were rare. One woman's chief complaint was that of urinary incontinence. She had previously had a perineorrhaphy without relief of this symptom. Following the removal of a very large spleen, this distressing feature was immediately relieved and has remained so. Presumably this was caused by the enlarged spleen pressing on the bladder. It has been something of a surprise to us to find that urinary symptoms are not more frequent.

Cardiac symptoms are seldom seen in the disease. In three cases presenting severe anemia and no apparent heart lesion, dyspnea occurred. Palpitation and precordial distress were present in one case.

We have not been able to correlate symptomatology with the stage of the disease. Patients frequently present themselves with few symptoms and at operation a combination of several advanced lesions is found.

2. Klemperer, Paul: Cavernomatous Transformation of the Portal Vein, Its Relation to Banti's Disease, *Arch. Path.* 6: 353 (Sept.) 1928.  
3. Brahme, L.: Ein Fall von chronischem Portalhinderniss, *Acta med. Scandinav.* 61: 175, 1924.

of the splenic vein, and one case of cavernomatous transformation of the portal vein.

In seven of the nine cases of Laënnec cirrhosis and the two unclassified cirrhotics the diagnosis was confirmed by liver biopsy.

In our two cases of splenic vein thrombosis, one was post-traumatic and the other was without known cause. In both of these, venous dilatation occurred proximal to the occluded vessels.

One of our youngest patients had a most unusual lesion. At necropsy within two days following splenectomy a cavernomatous transformation of the portal vein was found. Marked dilatation of the splenic and gastric veins was observed and death was due to the rupture of esophageal varices.

Klemperer<sup>2</sup> reported a case of this rare condition and collected twenty-two additional examples. Of these twenty-three cases, twenty-two presented splenomegaly and all showed varying degrees of occlusion of the portal or splenic veins. Klemperer's patient had had a splenectomy for supposed Banti's disease several years prior to death.

Chart 2.—Preoperative blood counts are represented by unshaded blocks. The postoperative blood values (increment or decrement) at the time of the last follow-up visit are represented as shaded or cross-hatched blocks.

The two cases of schistosomiasis mansoni in our group represent the first two of a larger series to be reported by Dr. Whipple in a subsequent paper. The mode of infection and the pathology of bilharziasis are now well known. Faust, Jones and Hoffman<sup>20</sup> have shown that the maturing phase of the parasite in the human host takes place in the hepatic, portal and mesenteric veins. Following deposition of eggs in the liver, a pseudotubercle or fibrous nodule is formed. If the infestation is sufficiently heavy, a severe form of cirrhosis results. Coupled with this cirrhosis is a splenomegaly, and with the hepatosplenomegaly there is often a blood picture similar to that in Banti's syndrome. Oddly enough, this striking similarity of Banti's disease to the late visceral stage of schistosomiasis mansoni is one that has received scant mention. Bonelli<sup>21</sup> drew the clinical comparison but

concluded that the Banti-like picture in late schistosomiasis was on the basis of a toxin of intestinal origin. Girges<sup>22</sup> with his extensive experience in Egyptian splenomegaly includes Banti's disease as a differential diagnosis of the late stage of the disease.

During the past several years, those working in the Spleen Clinic have been conducting clinical and experimental studies in Puerto Rico, where schistosomiasis is endemic. We have been interested in studying the development of the hepatosplenomegaly under conditions in which a known parasite is the inciting cause of the liver cirrhosis. At operation in the two cases reported herein, a severe grade of liver cirrhosis was apparent and was proved by biopsy.

In summary, therefore, in our thirty-one cases there were fifteen in which no "obstructive factor" could be demonstrated at operation. Thirteen cases presented some form of liver cirrhosis. Two cases presented thrombosis of the splenic vein, and one a cavernomatous transformation of the portal vein.

#### THE RESPONSE TO SPLENECTOMY

All the cases recorded in the foregoing sections have been followed carefully and the response to splenectomy will be considered according to groups and in each instance the hematologic observations will be reviewed, the preoperative being compared with the postoperative level.

The follow-up results in the various groups can be traced in chart 1. The cases are retained in the groupings as previously described: (1) Laënnec cirrhosis, (2) unclassified cirrhosis, (3) schistosomiasis mansoni, (4) thrombosis of the splenic vein, (5) cavernomatous transformation of the portal vein, (6) obstructive factor not demonstrated.

It is immediately apparent that the poorest results appear in the group having Laënnec cirrhosis. There were nine cases presenting the combination of this type of cirrhosis and Banti's syndrome. The immediate hospital mortality included two cases, or 22 per cent. One of these patients died of hematemesis and one of surgical shock. The remaining five fatalities occurred in periods varying from three months to thirteen years. Four patients succumbed to severe hematemesis and the fifth had recurring ascites and died of hepatic insufficiency. In spite of the poor late results, 66 per cent of the group were well from periods varying from two to thirteen years following operation.

The outcome of the succeeding groups was obviously much more encouraging. The patients having the unclassified type of cirrhosis, schistosomiasis mansoni or thrombosis of the splenic vein have all done exceedingly well. As is seen in chart 1, these individuals have been entirely symptom free and have remained well for long periods.

The one patient with cavernomatous transformation of the portal vein had had repeated hematemesis for two years prior to operation and promptly succumbed to a similar massive hemorrhage forty-eight hours after operation.

Our last series of fifteen cases in which the "obstructive factor" could not be demonstrated gave a hospital mortality of two cases, or 13 per cent, and a late mortality of three cases, or 20 per cent. The remaining ten patients (66⅔ per cent) have with one exception continued in excellent health for periods up to ten

21. Bonelli, P.: Analogía entre la schistosomiasis mansoni y la enfermedad de Banti o anemia esplénica, Bol. Asoc. méd. de Puerto Rico 23: 251 (July) 1931.

22. Girges, Rameses: Schistosomiasis, London, John Bale, Sons and Davidsson, Ltd., 1934.

years.<sup>23</sup> The single exception has had a miserable clinical course punctuated by repeated hematemeses over a span of ten years and is still alive. The cause of death in the last series included one case each of hematemesis, hepatic insufficiency, brain cyst, cerebral thrombosis and surgical shock.

From the foregoing experience one is immediately impressed with the gravity of hematemesis as a prognostic sign. Of the eleven patients who had evidence of esophageal hemorrhage prior to operation, seven died of the same complication. We have accordingly accepted hematemesis as an ominous symptom and feel that in this type of case operation should be avoided.

Although thrombotic phenomena are reported as being frequent sequelae of splenectomy in Banti's syndrome, only one patient in this study had this complication. Rosenthal<sup>6</sup> has emphasized the danger of thromboses after splenectomy in the "thrombocythemic" form of Banti's disease. Our experience does not confirm this observation. Graham Bryce<sup>24</sup> has shown that an apparently unsuitable case with a normal platelet count can be safely steered through the danger of splenectomy and, conversely, a low platelet count prior to operation does not necessarily protect the patient from fatal thrombosis.

As a parallel to the clinical improvement in our cases there has also been a favorable response in the blood picture. From chart 2 it is seen that, following splenectomy, there is usually a rise of the erythrocyte count, the hemoglobin content and the leukocyte and platelet levels. The groups as listed 1, 2, 3 and so on correspond directly to the same numbered groupings in chart 1. It is of interest to note that the total leukocyte count usually remains at a fairly high level throughout life, averaging 12,000 per cubic millimeter.

#### COMMENT

Reviewing the previous data, we wish to stress the clinical sequence of events of three cases in which there is adequate knowledge of the etiology and progress of the disease.

The two cases of schistosomiasis presented the classic features of the visceral stage of the disease. The pathogenesis and pathology of this disease are now well known. In such cases as we have described, there is a cirrhosis of the liver and splenomegaly. The cirrhosis follows pseudotubercle formation around ova deposited in the liver. The parasite rarely reaches the spleen except in overwhelming infestations. In spite of the absence of ova in the spleen, a scarring of this organ occurs. Although the splenic picture has been explained on the basis of toxins liberated by the parasites as they inhabit the portal and mesenteric veins, we believe that the splenomegaly can be secondary to the liver cirrhosis and the resultant portal venous congestion. It is certainly noteworthy that this tropical disease can in its late stages so well mimic Banti's disease.

The third case of interest to us is one in which we had the good fortune to have the clinical picture develop under our own observation. The history of this individual included a severe abdominal injury, followed by the development of a traumatic pseudocyst of the pancreas. This was operated on two years after the injury. At this time the spleen was not enlarged and the blood picture was normal. One year

later (three years after the injury) the patient began to have severe pain in the left upper quadrant, weakness and then suddenly a hematemesis. At this time it was found that the spleen was markedly enlarged and that the blood changes were consistent with a diagnosis of Banti's syndrome. At operation, occluded splenic veins were palpable.

These three cases have been separately emphasized, as they seem to be supporting links in our chain of evidence to show that at least in some cases of Banti's syndrome a primary obstructive factor exists.

#### SUMMARY

In a group of thirty-one cases, similar characteristics were apparent. In all, a state of venous congestion existed, as was evidenced by the dilated, tense venous channels in the portal or splenic bed.

There were sixteen instances in which a specific "obstructive factor" could be demonstrated as the possible agent producing venous stasis. However, in fifteen cases no evidence of an obstructive mechanism could be found.

A state of "portal hypertension" probably is present in all cases of Banti's syndrome. Splenic venous pressure determinations have been done in a few selected cases. These have been consistently higher than the peripheral venous pressure.

Our clinical and pathologic studies have led us to believe that in some cases this "portal hypertension" is secondary to the various obstructive lesions as described, whereas in other cases this may occur, as intimated by McMichael, as a primary disturbance of the portal system without a visible obstructive factor.

We believe that the mechanical interference with the splenic circulation may result in so-called congestive splenomegaly. This in turn may affect the activity of blood formation with depression of the cellular elements in the blood.

Following splenectomy in any of the groups previously discussed, this inhibitory effect is apparently removed, permitting a gradual return of the blood values to normal.

The indications for splenectomy and the long term prognosis are dependent on the nature and severity of the "obstructive factor." Obviously splenectomy is contraindicated in the presence of severe liver damage. The late results of splenectomy in our cases with Laënnec cirrhosis have been poor. The results in the remaining groups of cases have been most encouraging.

180 Fort Washington Avenue.

23. Since the completion of this paper we have again seen patient 9 in group 6. It has now been sixteen years since the splenectomy. The patient is in excellent health; physical examination is negative and all blood values including the platelet count are normal.

Expert Witness.—By the middle of the seventeenth century (in England) . . . the expert, possessed of a certain skill and knowledge, ceased to be an adviser to the court and was presented by one side or the other as a witness to the jury. Thus, although the value of his knowledge was still recognized, he had now become a partisan, at least in the eyes of the jury. In view of the contentious nature of legal proceedings, it was to be expected that counsel would present only experts favoring their particular thesis. Quite aside from honest differences of opinion, the possibility of bias must be recognized, and the unfortunate though rarer incidence of venality must be admitted. On the whole, it is not strange that the method of partisan introduction of expert evidence has brought suspicion on experts in general, and that as long ago as 1843 we find an English court saying "Hardly any weight is to be given to the evidence of what are called scientific witnesses; they come with a bias in their minds to support the cause in which they are embarked." (Tracy Peerage Case, 10 Cl. & F., 154.)—Overholser, Winfred: The Place of Psychiatry in the Criminal Law, *Psychiatric Quarterly* 10:197 (April) 1936.

## RATE OF EXCRETION AND BACTERICIDAL POWER OF MANDELIC ACID IN THE URINE

HENRY F. HELMHOLZ, M.D.  
AND  
ARNOLD E. OSTERBERG, PH.D.  
ROCHESTER, MINN.

Last year we<sup>1</sup> presented data to show the minimal concentration of oxybutyric acid in urine and the optimal  $p_H$  of urine that were necessary to cause sterilization of urine that had been inoculated with various strains of organisms isolated from urine. This acid results from the incomplete combustion of fats when only extremely small amounts of carbohydrate are given. The so-called ketogenic diet is difficult for many people to take. Recent work originating in England and pioneered by Rosenheim<sup>2</sup> has resulted in the knowledge that mandelic acid, when administered orally, escapes metabolism or conjugation in the animal organism and is excreted in the urine by the kidney in a concentration sufficient for bactericidal action, provided the  $p_H$  of the urine is lowered simultaneously. This acid was chosen as a result of experiments with many organic acids.

TABLE 1.—Rate of Excretion of Mandelic Acid and the  $p_H$  of the Urine of a Dog Receiving a Continuous Intravenous Injection During Seven Hours of 700 Cc. of 1 per Cent Solution of Sodium Mandelate

Hours After Beginning Injection	Urine		$p_H$ of

4	112	0.98	7.15
6	245	0.50	6.49
7	101	0.50	5.83
Urea clearance after Injection:		Blood urea after Injection:	
27.1 cc. per minute		44 mg. per 100 cc.	
Urea clearance three days later:		Blood urea three days later:	
57.1 cc. per minute		30 mg. per 100 cc.	

N. B.: Same as table 1 in Proc. Staff Meet., Mayo Clin. 11:374 (June 10) 1936.

Methods for sterilization of urine in cases of infection of the urinary tract are undergoing change and there is a general trend toward establishment of a more simple type of therapy. As yet, the simplest type of therapy has not been found.

In this paper we present data descriptive of our experimentation on animals and of our clinical experience, demonstrating the rate of excretion of mandelic acid following oral ingestion by man and following intravenous injection into dogs of its sodium salt. We also present the result of observations establishing the concentration of acid and the  $p_H$  necessary for the urine to possess bactericidal activity against numerous strains of organisms isolated from the urine of individuals having infections of the urinary tract.

Mandelic acid was determined as recommended by Rosenheim. This technic yields slightly high results owing perhaps to extraction of small amounts of other organic acids. However, for the purposes at hand the

method is sufficiently accurate. Values for the  $p_H$  of the urine were determined by the quinhydrone-electrode technic.

In table 1 are given the rate of excretion of mandelic acid and the  $p_H$  of the urine of a dog that had received a continuous injection, during seven hours, of 700 cc. of a 1 per cent solution of sodium mandelate. It is evident that the concentration of mandelic acid reaches a value sufficient for bactericidal activity, provided the  $p_H$  of the urine is lowered to a value shown later to be the optimal one for bactericidal activity. The decrease

TABLE 2.—Excretion of Mandelic Acid in the Urine of a Patient Following Oral Ingestion of 5 Gm. of Mandelic Acid

Hours After First Dose	Urine	
	Volume of, Cc.	Concentration of Mandelic Acid in, per Cent

6	240	0.60
10	155	0.61
24	500	0.21

of concentration over a period of seven hours from 1.5 per cent to 0.5 per cent is caused by the diuresis produced by the injection of 700 cc. of fluid. The kidneys of this animal received a temporary insult, as is evidenced by the fact that the urea clearance after injection was lowered to 27.1 cc., with a value for blood urea of 44 mg. per hundred cubic centimeters. This urea clearance increased during the next three days to 57.1 cc., and the concentration of blood urea became 30 mg. in each hundred cubic centimeters. This is evidence of the fact that any injury that may be produced in the kidney is only temporary.

Table 2 demonstrates the excretion of mandelic acid in the urine of a man, following oral ingestion of 5 Gm. of sodium mandelate in one dose. Eighty per cent of the ingested mandelic acid appears in the urine within twenty-four hours and the maximal excretion occurs approximately two hours following oral ingestion of the acid.

Table 3 shows the rate of excretion of mandelic acid and the  $p_H$  of the urine of a patient who had ingested 3 Gm. of mandelic acid in the form of a 10 per cent solution of the sodium salt four times during the day,

and who also had ingested ammonium chloride as an acidifying drug to lower the  $p_H$  of the urine. This table illustrates the cumulative excretion of mandelic acid as various quantities are ingested and shows also that, although diuresis may be produced, the concentration of mandelic acid reaches a value in excess of 1 per cent.

Table 4 illustrates the concentration of mandelic acid and the  $p_H$  of the urine of a patient under prescribed treatment with ammonium chloride and mandelic acid

From the Section on Pediatrics (Dr. Rosenheim) and the Section on Clinical Biochemistry (Dr. Osterberg), the

1 per cent is maintained. These values have been shown to be most conducive to bactericidal activity. On the seventh day of treatment the ingestion of mandelic acid was stopped and the concentration in the urine was accordingly lowered considerably.

The bactericidal power of the urine was determined by the same methods that were employed in our earlier study<sup>1</sup> on beta-oxybutyric acid. Again we want to emphasize that control experiments show that, with the exception of *Proteus ammoniae*, we have not found gram-negative organisms isolated from urine of patients having urinary infections which were killed by a  $p_H$  of 5.0 in the absence of an organic acid (table 5).

The first series of experiments was done with urine from patients who received sodium mandelate, and the concentration of mandelic acid in the urine varied from 0.25 to 1.1 per cent. At a  $p_H$  of 5.0, mandelic acid 0.25 per cent is bactericidal for most organisms; at a  $p_H$  of 5.3, a concentration of 0.5 per cent is bactericidal, and at a  $p_H$  of 5.7 a concentration of 1.0 per cent is bactericidal (table 5). Just as is true of the bactericidal action of beta-oxybutyric acid, the lower the  $p_H$  the lower the concentration of acid necessary for bactericidal action. In a series of experiments in which a 1.0 per cent concentration of this acid was added to normal urine and in a series in which the acid was excreted in the urine in a concentration of 1.0 per cent after it had been administered by mouth, the bactericidal action corresponded very closely.

In the great majority of urinary infections the organisms are bacillary in type and in large measure are *Escherichia coli*, *Aerobacter*, *Proteus* and *Pseudomonas*. It was this group which was studied intensively. Ten strains of *Escherichia coli*, ten strains of *Aerobacter*, five strains of *Proteus ammoniae* and five strains of *Pseudomonas* were tested with concentrations of 0.25, 0.5 and 1.0 per cent mandelic acid at a  $p_H$  varying from 5.0 to 5.7. The strains of *Escherichia coli* and of *Proteus* ran true to form, as all the strains were killed at the same concentrations of acid and at the same  $p_H$  (tables 6 and 7). The ten strains of *Aerobacter* could be separated definitely into a group of three strains that were killed under the same conditions of concentration of acid and of  $p_H$  as the *Escherichia coli* and into a

group of seven strains that were killed only when the  $p_H$  of the urine was the same as that necessary to kill *Escherichia coli* but the concentrations of acid were higher, or when the  $p_H$  of the urine was lower and the concentration of mandelic acid remained the same (table 8). There was one strain that was killed only at a  $p_H$  of 5.3 and a concentration of 1.0 per cent mandelic acid. Of the ten organisms, four were motile and six were nonmotile. Of the strains of *Pseudomonas*, two corresponded to *Escherichia coli* and three to *Aerobacter* (table 9).

It is thus evident that *Escherichia coli* is uniformly killed at a certain  $p_H$  and concentration of acid and that

centration of acid or a lower  $p_H$  is required, or both are required. This no doubt accounts for the conflicting results that various observers have obtained in treating infections with *Aerobacter* and with *Pseudomonas* by means of the ketogenic diet. Apparently the organism most easily killed is *Proteus ammoniae*, as is seen in all the experiments. The acidity of 4.8 alone in some

instances completely sterilizes a heavily inoculated urine. The difficulty in the treatment of infections with *Proteus* is the inability to acidify the urine because of the tendency of *Proteus* to produce a strongly alkaline

reaction in the urine. The accompanying chart shows in a graphic way the relationship of concentration of the mandelic acid and the pH of the urine in its bactericidal effect for various bacilli.

The bactericidal effect of mandelic acid on a large series of coccus organisms has not been studied but several strains of staphylococci have been tested out in

individual experiments and in a general way have been found to correspond, in respect of their vulnerability, to the bacillary group (table 10). Clinically also two patients have been freed from infection with *Streptococcus faecalis* by treatment with mandelic acid. It will be necessary, however, to make further determinations with a larger series of organisms to see whether they all fall within the same general range.

In conclusion, two facts can be stated: 1. By oral administration of sodium mandelate, concentrations of the acid varying from 0.25 to 1 per cent can be obtained readily in the urine. In this range of concentration the acid will act bactericidally on most organisms at a pH ranging from 5.0 to 5.7. 2. Certain strains of *Aerobacter* and *Pseudomonas* are far more difficult to kill than is *Escherichia coli*.

## MANDELIC ACID AS A URINARY ANTISEPTIC

### A CLINICAL STUDY

GRAYSON CARROLL, M.D.

BRANSFORD LEWIS, M.D.

AND

LOUIS KAPPEL, M.D.

ST. LOUIS

It was shown as early as 1917 by Shohl and Janney<sup>1</sup> that the hydrogen ion concentration of urine affected the growth of bacteria, and they demonstrated that colon bacilli were retarded in growth in a urine of pH 5 or less and on the alkaline side of 9.2 or more. This fact has been utilized in the administration of ammonium chloride followed by methenamine intravenously or orally. The introduction of the ketogenic diet by Clark<sup>2</sup> and by Helmholz<sup>3</sup> in 1931 marked another step in the therapeutics of bacteriuria. Although the patient on a ketogenic diet developed a highly acid urine, it was soon found that the acidity of the urine, though helpful, was not the only factor in bringing about the growth-inhibiting effect but that some bactericidal substance was excreted (Clark, Dick, Helmholz<sup>4</sup>). A. T. Fuller<sup>5</sup> of the Barnhard Baron Memorial Research Laboratories of London started investigation to discover this effective agent. A chemical fractionation was carried out of a mixture of urines that were actively bacteriostatic. The removal of the urea, inorganic salts, phosphatides, proteoses, bases and amino acids did not reduce the bacteriostatic properties. After the lactic acid was removed, the levorotatory form of beta-oxybutyric acid was left, which was found to be the bacteriostatic property in the urine excreted by the patient on the ketogenic diet. Finding the amount of this substance to be small in the ketogenic urine, Fuller suggested giving it by mouth. Investigations carried

From the Urological Department, St. Louis University School of Medicine.

The authors were assisted by Dr. Hollis N. Allen and Dr. S. H. Gray, who performed the bacteriologic work, and Drs. Thomas Saam and James B. Harris, resident urologists, City Hospitals, who managed some of the cases submitted in this clinical study.

out by a number of clinicians demonstrated it to be ineffective, however. As Cook and Braasch<sup>6</sup> commented, "Theoretically, this substance would be completely burned up if the body is in a normal metabolic state. The utilization of the usual amount of ingested carbohydrate is ample to oxidize completely this fatty acid before it can be excreted by the kidneys." Braasch demonstrated, however, that the introduction of beta-oxybutyric acid with a  $p_H$  of 4 into an infected bladder produced negative cultures in the majority of cases, thus demonstrating clinically the bactericidal action of the product.

M. L. Rosenheim,<sup>7</sup> of the University College Hospital, London, found the next piece to the jigsaw puzzle. The possibility suggested itself that a keto acid or hydrox acid might be found that would combine effective bacteriostatic power with resistance to oxidation in the body. Such an acid, if excreted unchanged in the urine and if nontoxic, should be able to replace the ketogenic diet. A number of fatty acids suggested themselves but were found unsatisfactory. Mandelic acid, an aromatic acid, was shown in 1863 by Shotten to be completely unaltered in the urine following administration to a dog. Experiments carried out on a dog substantiated this report and large doses proved nontoxic. A preliminary report of the clinical application of mandelic acid appeared in the London *Lancet* of May 4, 1935. On this favorable report, we obtained mandelic acid.<sup>8</sup> We are now reporting our clinical experience with fifty cases of pyuria treated by mandelic acid, as prescribed by Rosenheim.

The results obtained indicate that there is a definite value in the drug, superior to all other forms of medication in urinary infections. In a surprisingly large number of cases in which a highly acid urine was obtained, the results were most gratifying. Most of the failures could be readily explained.

Patients with suprapubic tubes, retention catheters, sinuses, and so on, were improved but were not made bacteria and pus free. Cases of alkali-encrusted cystitis failed to yield because of the persistent alkaline urine. The condition of patients with retarded flow of urine, such as pyonephrotic kidneys and hydro-ureters, improved wonderfully with the administration of mandelic acid. In the preoperative prostatic cases the results were favorable but not always completely effective. Those cases in which a  $p_H$  5 was obtained cleared up promptly in most instances. Postoperative transurethral cases have responded favorably but much more slowly than cases of pyelitis.

Apparently the drug is most effective against the colon bacillus and less effective against the staphylococcus, *Bacillus proteus* and *Bacillus pyocyaneus*. Recurrence of pus and bacteria, after discontinuance of the medicine, occurred in some instances but yielded again promptly when again administered. Those negative to culture are more likely to remain so than those negative only to pus. In no instance have we noted any toxic effect or impairment of function during the use of the drug.

The treatment has been conducted in the following way: The urine was examined microscopically to determine the amount of pus and the morphologic appearance

of the infecting organism. Cultures of urine aseptically collected by catheterization were made prior to and following treatment: The acidity of the urine was determined by nitrazine paper (Squibb) and nitrazine colorimeter charts, which offer a very simple and clinically satisfactory method. The patient was immediately placed on an acid-ash diet and given two ammonium chloride tablets, 0.5 Gm., four times daily. The acidity of the urine was tested daily and when a  $p_H$  of 5.5 or better was attained, which usually occurred in twenty-four hours, mandelic acid was prescribed in the following formula: mandelic acid 48 Gm., sodium bicarbonate

\* Patient died of *Streptococcus viridans* septicemia.  
† Five years of age.

25.6 Gm., distilled water 480 Gm. A flavoring syrup to satisfy personal preference was added. In some cases nausea, diarrhea or dysuria occurred. This we considered to be due to the ammonium chloride rather than to the mandelic acid, since in changing to sodium biphosphate the mandelic acid could be continued. Wherever an alkaline condition persisted, a careful recheck of the food taken often disclosed the inclusion of orange or lemon juice, spinach, beans, molasses or olives in the diet. When these were removed and the acidifying agent increased, the proper  $p_H$  was established. The medication was continued in most cases for a week following the finding of a negative urine. If a recurrence developed the regimen was repeated.

Rosenheim, in a personal communication, states that he has been using the ammonium mandelate recently, which makes the urine acid without the necessity of using ammonium chloride. However, sodium mandelate

6. Cook, E. N., and Braasch, W. F.: Further Studies on the Use of Ketogenic Diet for Bacilluria, *J. Urol.* 33: 583 (June) 1935.

8. The entire material has been supplied by the Mallinckrodt Chemical Company, St. Louis, through the Johannes-Tate Pharmacy.

and ammonium mandelate are quite hygroscopic and decompose. This is particularly true of ammonium mandelate. The mandelic acid is quite stable and the most convenient form for the druggist.

The results obtained in some cases of chronic pyuria have been remarkable. Cloudy urine that has resisted all forms of medication has become crystal clear in four or five days. A brief citation of a few will convey the favorable impression which we have received with its use.

Mr. J. S. S. of Cairo, Ill., had a suprapubic prostatectomy performed in 1926 and always thereafter had pus in the urine provoking episodes of epididymitis or outbreaks of other

4.5, no pus, no bacteria and culture negative. Never before have we experienced such an early clearing up of urine following transurethral work.

The acute cases of pyelitis and cystitis are affected very promptly, as shown by the following:

Miss M. M., aged 22, complained of frequency and pain on urination, with urgency and pain in the left renal region. The day of the administration of the drug, July 12, the urine was acid, with a  $pH$  of 5.0. The pus was 3 plus, the micro-organism *B. coli* 2 plus, and red blood cells 1 plus. July 15, three days later, the urine was clear with no pus or bacteria microscopically examined and the culture was negative. She was dismissed July 19 with relief from all symptoms.

An analysis of the accompanying tables shows thirty-seven cases of *Bacillus coli* infection, embracing acute and chronic pyelitis, pyelonephritis, vesical diverticula, nephroptosis, renal calculus, prostatic hypertrophy with retention and cystitis. All these became microscopically clear under the treatment. Seven yielded positive cultures.

The average number of days of treatment required to produce negative urines was 7.1. The seven cases of coccic infections, although improved, were not made sterile. This group is too small to conclude definitely that this organism is altogether resistant, especially when they are reported as being affected in vitro.

Of the six cases of *Bacillus proteus* infection, only one was made sterile. The *proteus* organism, we find, is most resistant in the urinary tract. Eighty-one per cent of all colon infections treated resulted in sterile cultures. Practically all cases improved symptomatically and the urines became less cloudy. We conclude from this survey that a urinary infection of a colon bacillus type, in which a  $pH$  of 5.5 is obtained, may be expected to clear up with the administration of mandelic acid within four to twelve days.

It is highly important to emphasize that all these patients were subjected to careful urologic study and the original causative factor in producing the pyuria was recognized and treated in the realization that the

39	6	5.0	Sterile	Negative	Pyelitis, <i>B. proteus</i>

urinary infection. All forms of urinary antiseptics and dilutions failed to clear the urine. Mandelic acid was administered and in four days the urine was grossly and culturally negative.

Mrs. W. G. C., aged 69, came from Washington, D. C., for treatment of a chronic cystitis and trigonitis. Undernourished, hampered with sinusitis and chronic bronchitis, she resisted all efforts to stamp out this persistent pyuria. In five days after the administration of mandelic acid, the urine became clear and urinary symptoms improved. The urine, cultures of which five days previously yielded *B. coli* in abundance, was found normal and the patient returned home within ten days.

In March 1934 we performed a right nephropexy on Mrs. E. B., of East St. Louis, Ill., which relieved her attacks of right renal colic, but later she became afflicted with a left pyelitis and cystitis, which persisted unrelentingly with symptoms of frequency, urgency, and bearing down perineal pain. Her teeth were examined and treated, the tonsils removed and various shock medications, including typhoid serum and nearsphenamine, administered, but the symptoms persisted. The urine from the left kidney showed pus 2 plus, *B. coli* 3 plus. She was given ammonium chloride and mandelic acid and within four days the urine was clear of pus and bacteria, with a  $pH$  of 4.5 and alleviation of symptoms.

Mr. R. S. D., aged 38, had bilateral pyonephrosis with right renal calculi and persistent pyuria since first seen in 1932; the organism was *B. coli*. Since each kidney had a retention of about 20 cc., this case offered a good example of what effect the medication would have on a retarded flow of urine. The mandelic acid was started June 30, and on July 13 the urine was clear and negative to culture. The patient states that he feels much better and does not tire as easily. The urine was still clear one month after treatment.

Mr. B. F. E., aged 62, had hypertrophy of the prostate gland, causing  $2\frac{1}{2}$  ounces (75 cc.) of residual urine. The patient was first seen June 26, 1936, when the urine was alkaline with pus 2 plus and *B. coli* 3 plus, the culture showing numerous colonies of *B. coli*. The temperature ranged up to 101 F. Medication was started the same day. Five days later the temperature was normal, the urine showing only an occasional pus cell although the culture still showed colonies of *B. coli*. A transurethral prostatectomy was performed on July 2 and the mandelic acid resumed the next day. The catheter was removed the third day and the patient completely emptied his bladder, voiding very cloudy urine. August 12, however, the urine was clear. The laboratory reported the  $pH$

pyuria was only one manifestation of the trouble. The real value of the drug will be lost and actually be prejudiced if it is indiscriminately used before the diagnosis is made. Pyuria is only a "physical symptom" such as fever, and any physician who is content to give relief only temporarily is a questionable practitioner. Because of the apparent effectiveness of mandelic acid in inhibiting the growth of *B. coli*, this report should in no way be construed as indicating it as a panacea for all urinary ills; but we wish to show by the case reports that pyuria is the end product of many com-

plicated diseases the cure of which calls for more than the administration of mandelic acid by mouth. Manifestly renal stone, kinked ureter due to movable kidney, prostatic hypertrophy, bladder diverticula, and stricture of the ureter or urethra—all found in the group studied—required more than the administration of mandelic acid; but mandelic acid was found most helpful in decreasing operative risk, where indicated, making the patient more comfortable and shortening the length of illness.

It is evident from the report of Dr. Anson Clark, who performed experimental work on dogs, that caution should be exercised in giving the proper dose and in cases of lowered renal function.

## MANDELIC ACID IN THE TREATMENT OF INFECTIONS OF THE URINARY TRACT

EDWARD N. COOK, M.D.

AND

HENRY A. BUCHTEL, M.D.

Fellow in Urology, the Mayo Foundation  
ROCHESTER, MINN.

In recent years the treatment of infections of the urinary tract has taken on a more scientific aspect. The older empirical methods which were efficacious in alleviating symptoms have been supplanted by newer forms of treatment which have a logical and predetermined basis and the value of which has been proved.

Since Shohl and Janney<sup>1</sup> demonstrated that the growth of *Escherichia coli* was inhibited in urine at a  $p_H$  of 4.6 to 5.0, the question of combating infection of the urine has come steadily to the foreground. Clark<sup>2</sup> in 1931, searching for a means of acidifying the urine, used the ketogenic diet. Early observations soon revealed that a secondary factor was needed besides high acidity if bacillary infections of the urinary tract were to be eradicated. Fuller<sup>3</sup> proved this secondary factor to be beta-hydroxybutyric acid. Helmholz and Osterberg<sup>4</sup> have definitely shown that a certain concentration of this acid, which is an end product of the ketogenic diet, is needed along with a certain  $p_H$  of urine if negative cultures of urine are to be obtained.

As the ketogenic diet requires the most careful and skilful management if good results are to be obtained,<sup>5</sup> and as it often causes distressing general and gastrointestinal symptoms, a vigorous search has been going on for a simpler and more easily managed means of treatment which would obtain the same results. When beta-hydroxybutyric acid is given by mouth to patients on a normal diet, it is oxidized in the body to carbon dioxide and water. Rosenheim,<sup>6</sup> after experimenting with similar organic acids, found that mandelic acid could be given by mouth and could be recovered in the

urine unchanged. Helmholz and Osterberg<sup>7</sup> carried on a series of experiments in the laboratory and demonstrated very definitely that the usual bacilli found in the urinary tract were definitely killed by a 0.5 per cent solution of mandelic acid at a  $p_H$  of 5.5. As with beta-hydroxybutyric acid, a lower  $p_H$  will not require such a high concentration of the acid.

During the past twelve months we have been using mandelic acid or its derivatives with varying results. Our earlier work revealed its efficacy in approximately 50 per cent of cases, but later experience has shown that, with more careful management, better results may be obtained. We have given a 10 per cent solution of sodium mandelate, the dose being 1 ounce (30 cc.) before meals and at bedtime. On this regimen the patient ingests 12 Gm. of the drug daily. In order to render the urine acid, either ammonium nitrate or ammonium chloride was given in doses of from 4 to 6 Gm. each day. Patients were instructed to take only five glasses of fluid daily in order not to dilute the urine. The results obtained were as follows: Seventy-five patients were given the drug, and the urine of sixty-one of them, or 81 per cent, was rendered sterile.

In an attempt to obtain the desired acidity of the urine without using an additional acidifying drug, Holling and Platt<sup>8</sup> suggested the use of the ammonium salt of mandelic acid and reported good results in four cases. In one of these cases they found that the addition of ammonium chloride was required to obtain a satisfactory  $p_H$ . We have given a 10 per cent solution of the ammonium salt of mandelic acid to five patients, and in all but one case a satisfactory  $p_H$  was obtained without the addition of an acidifying drug. Another salt of mandelic acid is ethanolamine mandelate, and this too is designed to eliminate the use of a secondary drug. Ethanolamine mandelate was given to five patients, and negative cultures were obtained in three of these cases. In one case an acidifying drug had to be added.

Recently the ammonium salt of mandelic acid has been prepared in a 40 per cent syrup solution, and this has proved very efficacious. It was given to twelve patients with bacillary infections of the urinary tract, and in eleven of the cases the urine was sterilized. One patient required ammonium nitrate to bring about the desired acidity of the urine.

Offhand this form of therapy may seem extremely simple. The physician can write a prescription for mandelic acid and an acidifying drug and the cure is assured. This is not actually the case, however, and unless the physician is alert in his management of these patients and checks the  $p_H$  of the urine daily, he will be greatly disappointed in the results he obtains.

In using the ketogenic diet, the diet itself aids greatly in acidifying the urine; with mandelic acid therapy this factor is lacking, and, if the mandelate plus the acidifying drug will not bring about a high acidity, other means must be instituted. In a few cases hydrochloric acid by mouth has been sufficient to increase acidity; in other cases an acid-ash diet has been tried, with varying results, and in still other cases the addition of the ketogenic diet has been necessary before the  $p_H$  was low enough and bactericidal urine was obtained.

While mandelic acid therapy may supplant treatment with the ketogenic diet in approximately 75 per cent of the cases, it cannot replace it entirely. We believe the main reason for this is the question of maintaining high acidity of the urine, as discussed in the previous paragraph. In conjunction with the ketogenic diet, mandelic acid will be extremely helpful. Often with the diet alone we were able to gain satisfactory acidity, but the concentration of beta-hydroxybutyric acid was not great enough to render the urine bactericidal. The addition of mandelic acid salts in this group of cases has already proved of great value. In one case in which diabetes insipidus was present as well as a urinary tract infection and the patient was on the ketogenic diet, extreme dilution of the urine prevented a sufficient concentration of beta-hydroxybutyric acid to obtain the desired results. The addition of sodium mandelate while the patient was still taking the diet sterilized the urine. Here, either form of therapy alone would have failed but the two used together were highly successful.

The urologic indications for the use of mandelic acid are the same as those for use of the ketogenic diet. To date, bacillary infections are readily attacked with this form of therapy while coccic infections are not.

As with the ketogenic diet, treatment of bacilluria associated with stonc, stasis or marked prostatitis will be more difficult and will require the same thoroughness. The contraindications to the use of mandelic acid are also similar to the contraindications to the use of the ketogenic diet. However, in certain cases in which patients have gout, gastric or duodenal ulcer, or diabetes mellitus, when the use of the ketogenic diet is impossible, we believe that mandelic acid will be extremely beneficial and cause no distressing results. Helmholtz and Osterberg have already shown in studies on animals that excessive doses of the drug will destroy the renal function and even produce death. In a series of normal individuals who were given the drug to determine the normal rates of excretion, determination of urea in the blood and of phenolsulfonphthalein excretion in the urine were made before the patients took the drug and after a week's ingestion of 12 Gm. daily. At the end of the week the blood urea was found to be increased in all cases; the percentage of excretion of phenolsulfonphthalein was decreased. Whether or not this apparent decrease in renal function is attendant on a lowered intake of fluid or can be attributed to the drug itself we cannot say, but certainly we feel that one should be cautious in using the drug for patients who already have a reduced renal function and, particularly, for the aged. Further studies along these lines are now being conducted, and until experience with the use of this drug is greater, it must be used with care.

Most of our patients have taken mandelic acid or its derivatives without any untoward effects, less than 1 per cent having experienced any nausea or vomiting. Approximately one in ten have noticed some diarrhea, but in most of these cases it was of a mild character; a few patients, however, did have from eight to fourteen stools a day and administration of the drug had to be stopped for a while. Its administration was resumed again later in decreased dosage without producing any ill effects.

In conclusion, we again wish to call attention to the importance of close observation and careful management of patients being treated with mandelic acid if the desired results are to be obtained.

## EXPERIENCES WITH AMMONIUM MAX- DELTATE IN URINARY INFECTIONS

A REPORT OF RESULTS OBTAINED IN SIXTEEN CASES  
OF VARIOUS TYPES OF INFECTIONS REGARD-  
LESS OF THE EXISTING PATHOLOGIC  
CONDITION

LEO P. DOLAN, M.D.

TOLEDO, OHIO

The medical profession is occasionally presented with a new urinary antiseptic before sufficient time has elapsed to permit competent observers to test adequately its therapeutic results. For that reason some drugs are used indiscriminately in all types of urinary infection instead of being restricted to the specific infections for which they were originally intended. Through this practice they sometimes fall into disrepute because of seemingly poor results.

At the present time we are apparently on the threshold of another such possibility. Recently some well known research workers through a logical sequence of events and experiments have presented the medical profession with an oral medication that has given startling results in certain types of urinary infection. Yet it has not been sufficiently investigated by controlled clinical and laboratory study to warrant its general distribution and use under the unrestricted title of "urinary antiseptic." Such a general term will undoubtedly bring it into early disrepute because of failure in some cases even if it should not cause untoward results and complications.

Clark and Helmholtz<sup>1</sup> in October 1931 called attention to the value of ketogenic treatment in various urinary infections, and the Nesbit<sup>2</sup> modification of the ketogenic diet is well known. It is this modification that I have followed as a routine because of its greater simplicity and likewise because it is better tolerated. Although the ketogenic diet has given remarkable results in bacillary infection of the urinary tract, it is not entirely satisfactory because of the strict regimen and the nauseating ingredients. This often causes the patient to become lax in its routine and necessitates hospitalization in most cases. It then becomes an economic problem in order to obtain the desired results.

Just as the discovering of the bacteriostatic properties of beta-hydroxybutyric acid led to the use of the ketogenic diet in urinary infections,<sup>3</sup> so Rosenheim<sup>4</sup> and others followed through in their investigations to produce a like condition in the urine as that which resulted from the use of the ketogenic diet. It was known by these men that beta-hydroxybutyric acid could not be used by oral administration because it was metabolized by the body. The use of other organic acids in the treatment of urinary infections was tried without effect. Then Rosenheim reported that mandelic acid passed through the body unchanged. When excreted in sufficient concentration in a urine with an acidity below a  $pH$  of 5.3, it was sufficiently bacteriostatic to be of practical value and comparable to the use of the ketogenic diet.

Read before the Detroit Branch of the American Urological Association at Ann Arbor, Mich., Oct. 24, 1936.

4. Rosenheim, M. L.: *Lancet* 1: 1032-1037 (May 4) 1935.

Later in December 1935, Lyon and Dunlop<sup>5</sup> confirmed these observations and called attention to the use of mandelic acid salts.

In April 1936, Holling and Platt<sup>6</sup> reported twenty-nine cases treated with mandelic acid salts and suggested the use of the ammonium salts as preferable. Previously in the use of mandelic acid as such, sodium bicarbonate was given as a neutralizing agent or buffer. This in turn required the administration of ammonium nitrate or ammonium chloride in order to maintain the acidity of the urine below a  $p_H$  of 5.3, or the degree necessary to produce the best results. This combination often caused considerable gastric distress, nausea and sometimes vomiting of the drug.

In July of this year, Cook of the Mayo Clinic, in a letter to the Urologist's Correspondence Club, reported the use of 40 per cent solution of ammonium mandelate in five cases of urinary infection. Negative cultures were obtained in all cases. These patients were given an alkali-free diet, and their fluid intake was limited to one liter daily. Interested by this report, we decided to try it. We were confronted, however, with the fact that such a drug was not available commercially in the United States, though it was available in England in the form of sodium mandelate. Through the cooperation of a local chemist mandelic acid was obtained, and from this he made up ammonium mandelate, but to make it more palatable a 40 per cent elixir was prepared. This preparation has been well tolerated by all our patients. At the present time several of the larger pharmaceutical houses either have mandelic acid preparations on the market or are preparing to announce them.

We have used ammonium mandelate in various types of urinary tract infections both in our office and in our hospital practice, and we offer a summary of the results obtained in sixteen cases which we have treated.

In using this treatment the patients are given 2 drachms of the 40 per cent elixir of ammonium mandelate, which amounts to 3 Gm. (7.5 cc.) of mandelic acid, four times daily in a small quantity of water. The total fluid intake in twenty-four hours should not exceed 1 liter of fluid, actually measured at the beginning of each twenty-four hours and evenly distributed to maintain a balanced concentration. The patient, if not hospitalized, is cautioned against the use of all other drugs, also foods and fruit juices, which might readily produce an alkaline urine. No other restrictions seem necessary. If the patient is not physically incapacitated he may carry on his usual occupation. We have maintained, however, a close check on each patient with a daily cell count of the urine and a  $p_H$  determination. This observation is obviously necessary for proper control of the case.

One of the fundamental principles in the treatment of urinary tract infections is the elimination of existing obstructive lesions and the establishment of free drainage. The first case in our series presented such a marked degree of renal ptosis and obstruction, as shown by the pyelogram, yet such striking results were obtained on ammonium mandelate therapy, that I will report it in detail. I am doing this so that other physicians also will be favorably impressed as my associates and I were, for this case offered us moral support in the face of failures encountered in some other types of infection.

## REPORT OF CASES

CASE 1.—A white woman, aged 67, who was very emaciated and confined to her bed, was first seen on Aug. 4, 1936, because of pain in the region of the bladder and urethra, frequency of urination accompanied with burning, and pain in the back, particularly over the right lumbar region. These symptoms had been present with increasing intensity during the previous several months. Cystoscopic examination revealed the bladder urine to be turbid with pus. A large amount of grayish debris was hanging from the bladder walls, and the blood vessels of the bladder mucosa were markedly congested. On ureteral catheterization, clear urine was obtained from the left kidney while turbid urine containing approximately 200 pus cells per low power field was obtained from the right kidney. The cultures from the right kidney and bladder yielded colon bacilli. The left kidney culture was sterile. Pyelography demonstrated a normal left kidney and a large, hydronephrotic, ptosed right kidney. The ptosis was of such a character that the pelvis did not have free drainage from the position in which it reposed. More than 150 cc. of purulent urine was aspirated through the right ureteral catheter before the contrast medium

Fig. 1 (case 1).—Right pyelo-ureterogram showing marked dilatation and ptosis, and obstruction at the ureteropelvic junction.

was injected for pyelography. The ureteral catheter was fixed in place for drainage and pelvic lavage of the right kidney was carried out at frequent intervals over a period of several days. Various urinary antiseptics were given by mouth but this treatment proved valueless, for when the catheter was removed seven days later the symptoms recurred. An intravenous urogram August 12 showed the right kidney to have fair function but no change in the hydronephrosis. Nephrostomy, nephropexy and nephrectomy were considered but, owing to the poor general condition of the patient and her aversion to surgery, we decided to try the ammonium mandelate therapy first. The treatment was started August 24 at which time the urine contained from 15 to 20 pus cells per high power field, uncentrifuged urine. August 26 a voided specimen showed 8 to 10 pus cells per high powered field. September 1 the cell count was about the same, with some granular casts being present. September 10, sixteen days after starting the therapy, 2 pus cells per high power field were found. The urinary symptoms had disappeared except for some burning on urination. The  $p_H$  of the urine had varied from 4.5 to 5.3 throughout the treatment. September 15, twenty-one days after the medication was started, there were but slight urinary symptoms and the general condition was improved. The remarkable absence of pus in the

6. Holling, H. E., and Platt, Robert: Lancet 1: 769-771 (April 4) 1936.

bladder urine made us skeptical of a possible painless blocking of the right ureter. We therefore catheterized the right kidney and found no pus in the urine from this side and a sterile culture was obtained. Examination of the urethra showed it to be inflamed and edematous, this apparently being the cause of the burning on urination. For the last month the patient has been up and around her home without pain or symptom and the urine is still free of pus.

CASE 2.—As the results in our first case were so striking and were evident so early in the treatment, we felt that we might try it in a mixed type of infection. An elderly, prostatic patient two years previously had suffered an apoplectic attack, which confined him to his bed with a right sided paralysis, difficult speech and acute retention of urine. At the time we saw him, during the early days of his paralysis, the urine was purulent and a retention catheter was fixed in place. After prolonged hospitalization, the patient was able to be up and about, unassisted. The urine, however, remained turbid with infection and he was under constant treatment of bladder irrigations and oral urinary antiseptics. His prostate was markedly enlarged. It was smooth, firm and not sensitive. No nodules were palpable. Cystoscopic examination showed the

Fig. 2 (case 15).—Upright pyelo-ureterogram (retrograde) showing ptosis and obstruction with dilatation of right kidney pelvis and ureter.

blood vessels of the bladder to be congested and the bladder walls trabeculated. There was a massive intravesical encroachment of both lateral lobes of the prostate. Because of the patient's general condition we had advised against operative procedure. Aug. 31, 1936, we started this patient on ammonium mandelate therapy, at which time the urine contained 150 pus cells per high power field and the culture of the urine yielded staphylococci. September 2 the amount of pus had not changed. September 8 the pus had decreased to from 50 to 60 pus cells per high power field but there was present also some 60 to 75 red blood cells. The patient also was complaining of considerable gastric distress and loss of appetite. It was learned that he was taking the ammonium mandelate undiluted, which may have accounted for the severe gastric distress; but it would not account for the blood cells in the urine. The  $pH$  value was maintained at 5.5 or below. September 10 the condition was better. The urine contained around 40 to 50 pus cells and about the same number of red blood cells per high power field. September 13, two weeks after treatment was started, the patient had taken 16 ounces (475 cc.) of the elixir of ammonium mandelate. A check of the urine showed 150 pus cells present per high power field. There was an occasional red blood cell present. This was thirty-six hours after the medication had been stopped, and the  $pH$  of the urine had risen to 6.0. The

following day the patient had an acute retention of urine and in general had lost ground in physical strength throughout the course of the treatment. Several days of palliative treatment were given. A retention catheter was used, but the patient was unable to tolerate it and a cystostomy was done for relief. A transurethral resection is now contemplated, since suprapubic drainage is established. This patient, we feel, was not benefited by the treatment and complications were encountered.

CASE 3.—A white man, aged 72, was first seen Jan. 22, 1936, because of urinary obstruction, which had been present in an increasing degree for the past ten years. During the previous three months occasional attacks of hematuria occurred. Rectal and cystoscopic examination revealed a large prostate, grade 3 in size, with an 8 ounce (235 cc.) residual urine. Many small stones were present in the bladder and marked edema of the floor was present also. A two stage suprapubic prostatectomy was performed. Convalescence was slow but uneventful. He left the hospital seven weeks after admission and returned to the office for further treatment. His condition improved rapidly. He voided freely; nocturia disappeared. He regained his weight and strength and returned to his work. There were no symptoms of any type and no residual urine, yet in spite of bladder irrigations and prolonged use of various urinary antiseptics the urine remained turbid with pus and colon bacilli. There have been no symptoms of kidney infection at any time. An x-ray film of the kidney, ureter and bladder was negative for stone shadows. Ammonium mandelate therapy was started August 22, at which time the urine contained colon bacilli and from 25 to 30 pus cells per high power field and a  $pH$  of 7.0. August 24, two days after treatment was started, the pus had decreased to an average of 18 cells per high power field. September 1 it was reduced to from 2 to 4 cells per high power field. September 9, two days after the treatment had been stopped, it contained from 8 to 12 pus cells per high power field and, on staining, various types of bacteria were found. Through the course of treatment the  $pH$  remained at 5.0, while a few days after treatment was stopped the  $pH$  rose to 7.5. This is a case which was undoubtedly aided by the mandelic acid therapy. The colon bacilli were eliminated while other organisms appeared later. This patient lives 50 miles from the city and it is difficult to maintain him on a routine which we desire, but I believe that, if this patient is placed on treatment under different circumstances for a sufficient period, his condition will be greatly improved.

CASE 4.—A white woman, aged 27, was first seen Aug. 1, 1936, on account of pain in the right kidney region, which was intermittent in character. These symptoms had been present for two years but had not been severe until three months previously. Cystoscopy and pyelography at this time showed a normal bladder with a moderately dilated right kidney pelvis, the condition apparently being due to a constriction at the ureteropelvic junction. Urine specimens from the kidney produced negative cultures, and an upright pyelo-ureterogram showed no ptosis of the kidney. Following the examination, the patient's symptoms were greatly aggravated. There was an elevation of temperature, and pus and blood appeared in the urine. We felt that we had introduced an infection into a partially blocked kidney. She was kept at bed rest on urinary antiseptics and forced fluids. After a period of two weeks when she was feeling better we dilated the right ureter to a size 14 F. Urine obtained from the left kidney at this time was negative, while the right side showed pus and staphylococci. After this dilation there was again an aggravation of symptoms, which subsided after a few days of bed rest and urinary sedatives, but the original symptoms persisted. We started giving ammonium mandelate August 29, at which time a specimen of urine showed a  $pH$  value of 6.0 and contained from 4 to 6 pus cells per high power field. The culture yielded staphylococci. During treatment the  $pH$  varied from 4.5 to 5.5. The number of pus cells ranged from 2 to 8 per high power field. After two weeks of ammonium mandelate therapy the urinary examination gave approximately the same results as the day on which it was started. In this case I feel that the therapy was of no value. After the therapy was stopped, the patient's general condition improved under forced fluids and an increased diet. This was followed by a gradual diminution of pus in the urine.

CASE 5.—This case is of interest because of its long standing history. A man, aged 61, was first seen in 1932 because of

hematuria and pyuria and symptoms of obstructive urination. These symptoms had been present at intermittent intervals over a period of several years. Cystoscopy and cystography in 1932 revealed a large intravesical prostate, marked trabeculization of the bladder with multiple small diverticula, and one large diverticulum which was practically the size of the bladder. Prostatectomy and diverticulectomy were subsequently done and the patient had a prolonged convalescence. For many weeks after leaving the hospital he was treated with bladder irrigations and urinary antiseptics but the urine persisted to be turbid. Cystoscopy revealed the large diverticulum to be absent, but the smaller ones remained about the same size. Though the patient remained well for the intervening time from 1933 to the present, the urine never changed in character. Sept. 15, 1936, he returned to the office for routine examination and it was decided to try him on ammonium mandelate. Culture of the urine showed gram-positive bacilli and diplobacilli. The  $pH$  before the treatment was started was 7.0. Two days after it was started the urine was clearer than at any time in many years of the patient's memory. The  $pH$  was 4.5 and there were from 4 to 6 pus cells per high power field. The patient continued on the treatment for only twelve days, as his business required a long absence from the city. Throughout his treatment the  $pH$  value of the urine varied from 4.5 to 5.0. At the time of the discontinuance of the treatment the urine still contained an occasional pus cell per high power field and some bacteria were still present in a smear. This case I feel will probably go on to a possible cure when the patient returns for further treatment.

CASE 6.—The sixth case is of interest because the culture of the urine before the therapy was started contained diplococci and streptococci. A man, aged 61, was seen because of symptoms of urinary obstruction. A transurethral resection of the prostate was done June 30, 1936. He made an uneventful recovery from this. There was no residual urine. He had frequency of urination of three to four times a day and nocturia from one to two times, when seen September 19. The urine remained turbid in spite of frequent bladder lavage and oral urinary antiseptics. The  $pH$  of the urine was 7.0. He was started on ammonium mandelate on this date and two days later, September 21, the urine appeared clear. There was an average of only one pus cell per high power field, and the  $pH$  was 5.0. As the patient was complaining of loss of weight while on treatment and because of the apparent cure, I felt justified in stopping the therapy at this time. Five days later, however, he returned to the office and the urine was again hazy with pus and bacteria. The  $pH$  was 6.0. Ammonium mandelate was resumed, and October 10 the urine was clear with a  $pH$  of 5.0 and there was an average of about 1 pus cell to every two or three high power fields. October 14 the urine was sterile, but the treatment was continued for five more days. This made a total in this case of 6 ounces (180 cc.) of 40 per cent ammonium mandelate in the first course of treatment and 16 ounces (475 cc.) in the second and last series. October 22, two days after discontinuance of the drug, the patient returned to the office with a slightly hazy urine containing many bacteria and a rare pus cell. Cultures taken at this time have not yet been reported. This infection seems to show marked resistance to the treatment. At least recurrence appeared soon after the treatment was stopped. I believe that better results could be obtained in this case with the use of additional ammonium chloride to maintain the  $pH$  around 4.5.

CASE 7.—A man, aged 49, seen first Oct. 2, 1936, with symptoms of acute cystitis, was hospitalized and on October 5 urologic study revealed a marked cystitis suggestive of tuberculosis. Pyelography showed slight irregularity in the minor calices of the left kidney similar to that sometimes seen in early tuberculosis. Urinalysis demonstrated many pus cells from both kidneys. Culture of the left kidney yielded staphylococci and of the right kidney diplobacilli. No tubercle bacilli were found in smears. Guinea-pigs were inoculated with separate urine specimens. The patient was placed on ammonium mandelate therapy and allowed to return to his home in another city under the supervision of his local physician. One week later the physician reported all symptoms worse and hematuria present. The therapy was discontinued and palliative measures were instituted. Seventeen days later the guinea-pigs are still alive, but not ready for autopsy; still I feel that, clinically this is prob-

ably a case of renal tuberculosis. The irritability of the urinary tract on acid treatment seems to substantiate this diagnosis.

CASE 8.—A man, aged 75 on whom a prostatic resection was done in August 1935, had a resulting residual pyuria of 20 cc. Routine treatment did not change this condition nor did the absence of treatment alter the urine. September 24 he was first given ammonium mandelate, when culture showed *Bacillus coli* present. October 19 the culture was sterile and the urine was hazy with red blood cells, which averaged 8 per high power field. Treatment was discontinued. This patient was on treatment twenty-five days. The blood appeared the last three days. The prolonged treatment was probably due to the fact that the  $pH$  remained above 6.0 during the first eight days. He admitted that during the first week he was taking more than the prescribed amount of fluid.

CASE 9.—This is a case of hypertrophied prostate and diverticulum in a man, aged 71. The prostate was resected July 14, 1936, in the face of a diverticulum with a capacity of approximately 60 cc. The patient made an uneventful recovery except for the remaining pyuria, which was unaffected by treatment.

Fig. 3 (case 16).—Pyelogram showing marked dilatation and ptosis of right kidney.

*Bacillus coli* appeared in cultures from the urine October 2, and the patient was started on ammonium mandelate. Five days later the urine was clear with 1 or 2 pus cells being present per high power field. On the tenth day cultures were sterile, but from past experience treatment was continued for three more days and the patient now is on observation apparently cured, though nothing was done to the diverticulum, which was located on the floor of the bladder.

CASE 10.—This case is interesting because of the differential diagnosis. The patient was sent into the hospital by a gynecologist because of pain in the right lower quadrant and pus in the urine. He was satisfied that the right adnexa were normal. She had an appendectomy two years previously. On admission to the hospital a catheterized specimen of bladder urine was obtained and a large amount of pus was found; likewise the culture showed diplococci and diplobacilli. The patient was started on ammonium mandelate without further examination. Thirty-six hours later, as the pain still persisted and the temperature remained at 102 F., where it had been on admission, we were stampeded into doing a ureteral catheterization. This was the first case of acute pyelitis in which we had used this therapy and we were willing to be stampeded. The catheterized

urine from the kidneys showed no pus and no cultural growth from the left side, while from 30 to 35 pus cells per low power field were obtained from the right kidney and the culture showed diplococci and diplobacilli. Against advice, we removed the catheters from the kidneys and continued the mandelic acid therapy. Two days later the temperature dropped to normal. The catheterized specimen of urine from the bladder showed from 1 to 2 pus cells per high power field and a  $pH$  of 4.5. The following day the patient was allowed out of bed and on October 13, six days after the therapy was started, the patient was allowed to go home. A culture at that time was sterile. On October 22 the patient had no complaints, the temperature remained normal and the urine was free of pus.

CASE 11.—A man, aged 72, entered the hospital suffering from pain in the right lumbar region radiating inferiorly and anteriorly. Examination revealed a calculus in the right renal pelvis, another in the right lower ureter near the ureterovesical juncture and two in the left lower ureter, and one in the bladder. Each was approximately the size of a small green pea. The patient also had a hypertrophied prostate with both vesical and urethral encroachment. The ureteral and bladder calculi were delivered by cystoscopic manipulation and a trans-urethral resection of the prostate was subsequently done. The patient left the hospital with a calculus still remaining in the right renal pelvis and a urine cloudy with pus and colon bacilli. This was in June 1936. Routine treatment did very little toward clearing the urine. Ammonium mandelate was first given October 14. Five days later the urine was clear and cultures were sterile.

CASES 12 AND 13.—In these two cases we used the ammonium mandelate very closely following transurethral resection of the prostate. The first patient was a man, aged 81, and treatment was started ten days after operation while he remained in the hospital making a very slow recovery. The culture yielded staphylococci. The patient was on treatment six days without apparent change in the urine. Because of dehydration he was removed from this therapy.

The second case, in which therapy was started soon after resection of the prostate, gave a culture of *Streptococcus viridans*. Treatment was started three days after resection. Bladder irrigations were used in conjunction in both cases. On the fourth day of treatment, seven days after resection, improvement was noted but a secondary hemorrhage occurred which necessitated discontinuance of the treatment.

CASE 14.—A hospital orderly, aged 25, had a known pyuria prior to a gonococcal infection with accompanying epididymitis. He had been in the hospital ten days when I first saw him. The gonorrheal infection was in a subacute stage and the epididymitis was subsiding. Voided specimens of urine were cloudy with pus. No cultures were made but the patient was put on mandelic therapy to see if it might give any clinical results. It did. After twenty-four hours of administration of ammonium mandelate, it was discontinued because of the onset of severe urethral irritation.

CASE 15.—The next two cases are somewhat similar because they show the same pathologic type, which consists of a right sided pyelonephritis and posed, hydronephrotic right kidney. Both have purulent pus in the right kidney. These cases were seen on the same day. The first one, on cystoscopic examination, showed from 6 to 8 pus cells per low power field in the left kidney and about 700 or 800 per low power field in the right kidney. Both cultures yielded were colon bacilli. The pyelograms (figs. 2 and 3) reveal the type and degree of hydronephrosis and ptosis. Both cases evidently show stasis. Patient 15 entered the hospital for urologic study, after which she was started on ammonium mandelate October 1. Two days later she left the hospital and returned to the office, stating that she felt much better. The urine appeared to be much clearer in a voided specimen. The  $pH$  was 5.5. October 5, five days after treatment was started, a catheterized specimen of urine was clear. There were from 2 to 3 pus cells per high power field. The  $pH$  was 5.0. The patient stated that she had not felt as well in many weeks. October 7 the  $pH$  was 5.0 and no pus was found. October 9, which was the ninth day of treatment, sterile cultures were obtained. No pus was present in the urine. The patient had taken only 8 ounces (235 cc.) of the medication, but, because of her excellent condition, treatment was discontinued. She returned for repeated examinations and on

October 21 the urine was still free from pus, the  $pH$  was 7.0 and she stated that she felt better than she had in a long time.

CASE 16.—This is the second of the cases examined on the same day. It was stated that the pathologic condition was similar except that this patient was an older woman, aged 76, who had been ill for months. It was said that she was known to have diabetes, which makes it interesting because diabetic patients are considered to have less infection, owing to the ketone bodies in the urine. However her blood sugar was only 148 mg. and she had a one plus sugar in the urine. The pyelograms in this case show that there is even a more marked ptosis and hydronephrosis than there was in the preceding case. At the time of cystoscopy a cell count of from 8 to 10 per low power field was found in the left kidney urine and 200 or more in the right kidney specimen. Treatment was started October 1, and within seventy-two hours, without any other acidifying measures except the 40 per cent elixir of ammonium mandelate, the  $pH$  of the urine dropped from above 7.0 to 5.0 and there was only a slight haziness to the urine.

Here the case became more interesting because on the third day after treatment was started the laboratory reported on the cultures made prior to treatment. The report was *Bacillus proteus*. Chute's<sup>7</sup> warning was recalled concerning the possibility of formation of urinary calculi when attempting to acidify a proteus infection because of the urea splitting properties of this bacillus, which produces ammonia. The urine thus made more alkaline would be predisposing to the formation of calcareous deposits. However as the  $pH$  was 5.0 on the third day of treatment and the urine contained less pus, it was felt that we were justified in continuing the administration of ammonium mandelate. Seven days later the urine showed only 1 or 2 pus cells per high power field and the patient was feeling better in general, and though she had been bedfast for several weeks she was sitting up in a chair. The pain which she originally complained of in the right lumbar region had disappeared. October 13 an intravenous urogram was made. The blood chemistry showed a decrease in the sugar from 148 mg. to 120 mg. The nonprotein nitrogen decreased from 47 mg. to 35 mg. The intravenous urogram showed normal functioning of both kidneys with the same degree of dilatation and ptosis as previously seen. The urine culture is sterile and no pus is present in the specimen. She was taken off all therapy and given an unrestricted diet. She left the hospital October 20 with an increase in weight of 10 pounds (4.5 Kg.).

#### SUMMARY

The results obtained with the use of ammonium mandelate in treating sixteen cases of various types of urinary infection, regardless of the existing pathologic condition, may be thus summarized:

1. Seven cases of *Bacillus coli* infection resulted in six apparent cures and one partial cure with complications of hematuria in one case. There were no failures.

2. Three cases of staphylococcus infection resulted in three failures. One complicated with hematuria was followed by acute retention in a prostatic case with previous cerebral involvement.

3. One case of *Streptococcus viridans* infection was slightly improved.

4. One case of mixed infection of diplococcus and *Streptococcus viridans* resulted in apparent cure but there was a recurrence.

5. One case of diplobacillus infection resulted in apparent cure.

6. One case of mixed infection of staphylococci and diplobacilli and possibly tubercle bacilli resulted in failure with aggravation of all symptoms.

7. There was one mixed infection with gonorrhea in which treatment was not tolerated.

8. One case of *Bacillus proteus* infection resulted in apparent cure.

## COMMENT

Rosenheim, in his study of mandelic acid treatment, concludes: "Mandelic acid appears to be effective in cases of urinary infection unassociated with urinary obstruction." It would seem that the explanation of apparent cure resulting in three cases, here reported, of marked obstruction is the fact that the drug is held longer in situ, thus giving its bacteriostatic powers longer time in which to function. The same reasoning seems logical in the cases of diverticula of the bladder in which such good results were obtained.

Because of the short period of time in which these cases have been observed, the good results have been designated as apparent cures only. Experience has shown recurrence in some cases.

Because of the increasing distribution of this drug for general use, without warning of possible complications, attention should be called to the complications encountered in this series of cases.

NOTE.—Since the presentation of this paper, personal communications from three other urologists, using ammonium mandelate from different pharmaceutical houses, have reported four cases of hematuria during its use.

## AIR-BORNE INFECTION

## SANITARY CONTROL

WILLIAM FIRTH WELLS, B.S.

AND

MILDRED WEEKS WELLS, M.D.

CAMBRIDGE, MASS.

In view of the proved possibility of infectious matter being carried by air, reasonable efforts to free air supplies from living micro-organisms are justified in the light of general sanitary principles. The great reduction of intestinal disease through water purification since the turn of the century might prompt us to hope that some of the diseases transmitted through discharges from the respiratory tract may be checked by methods of controlling air supplies. A study of the effect of ventilating factors on the dispersion and viability of micro-organisms suspended in air<sup>20</sup> has already disclosed the efficacy of certain destructive agencies.

Experiments on the disappearance of *B. coli* in the recirculated air of an air-conditioned room were conducted as a preliminary to the investigation of textile mill humidification referred to previously.<sup>12</sup> *B. coli* seemed to disappear much more rapidly from air when the spray humidifier was operating than when the air was recirculated without the use of the spray. Further tests showed that the reduction in the number of bacteria did not take place in the spray chamber but after the air had returned to the room, indicating that humidity might increase the death rate of *B. coli* in the air. Increasing relative humidity from 45 to 90 per cent more than doubled the disappearance of *B. coli* from air.

By means of the technic developed in this study, experiments on other physical and chemical factors were undertaken with the technical assistance of R. F.

Second part of a paper read before the Harvard University Tercentenary (1636-1936) Symposium on "The Environment and Its Effect upon Man" at the Harvard School of Public Health, Aug. 24, 1936. The first part was published in *THE JOURNAL*, November 21, p. 1698.

20. A grant from the Milton Fund for studies on the defects of ventilating factors on dispersion and viability of micro-organisms suspended in air was made by Harvard University.

Wagner. Ozone in tolerable concentrations was found to give effects of a similar order of magnitude; i. e., olfactory concentrations four times the threshold value raised the death rate threefold. Commercial germicidal sprays also gave somewhat similar results. Negative and positive ions produced no observable differences in disappearance rate. The bactericidal action of a quartz mercury vapor lamp, however, was of a higher order of magnitude.<sup>21</sup>

The bactericidal effects of ultraviolet radiation on micro-organisms suspended in air proved to be of a higher order of magnitude than humidity, ozone or commercial germicides.

*Effect of Ultraviolet Radiation.—Physical Factors:*<sup>22</sup> These results precipitated an intensive investigation of

Fig. 2.—Bactericidal action of ultraviolet radiation on *B. coli* in air at different distances.

the physical and biologic factors governing the effect of ultraviolet radiation on micro-organisms suspended in air.

The interrelationship of space and time involved in the application of light to the sterilization of large volumes of air present mathematical problems hitherto unfamiliar either to sanitary science or to the science of illumination. In chemical disinfection, a relatively uniform concentration of active reagent is assumed for a disinfecting interval. In thermal sterilization or pas-

22. Wells, W. F.: Some Basic Physical Factors Governing the Bactericidal Action of Ultraviolet Radiation on Micro-Organisms Suspended in Air. *J. Bact.*, to be published.

teurization, each organism is subjected to a fairly uniform temperature for a specified interval of time. Where light has been used in the sterilization of liquids, a relatively thin film of exposure is necessary for effective action, so that each organism may be considered to be exposed to a relatively uniform degree of intensity of light for an adequate time interval. In attempting to

Preparatory to a more thorough analysis, and also to experimental application of light, studies were undertaken in the tunnel system of the Harvard School of Business Administration. A quartz mercury vapor lamp was placed in the center of this tunnel, which was 100 feet long, 8 feet wide and 7 feet high. Air inoculated with *B. coli* could be drawn down this tunnel at regulated velocities and the bacterial concentrations at different points determined by simultaneous sampling with three air centrifuges.

The bactericidal reductions at flows above 20 feet per minute were too low for accurate determinations in approaching to within 5 feet from the light. Measurable reductions in bacteria were obtained with low air flows, but these low flows could not be accurately measured. At 6 feet per minute, bactericidal reductions could be determined and the flow measured with a reasonable degree of accuracy. The results of such a test are illustrated in figure 2. Marked reductions are apparent up to within 5 feet from the light, and noticeable effects as far as 55 feet from the light. Precise results could not be obtained by this method in the tunnel arrangement, though a more precise laboratory arrangement utilizing closer approach was later developed by Benjamin Whisler<sup>23</sup> in a study for a doctor's thesis.

Obviously the zone of greatest bacterial reduction lies within the sections 5 feet before and beyond the light.

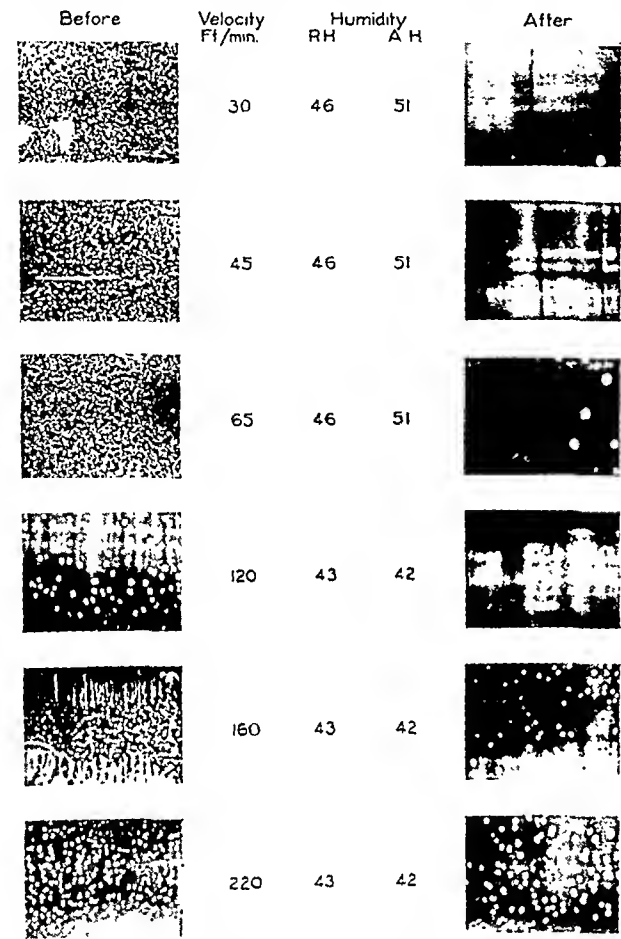

Fig. 3.—Bactericidal action of ultraviolet radiation on *B. coli* in air at different velocities. Passing light

sterilize by ultraviolet rays the large volumes of air involved in practical ventilation, it becomes difficult if not impossible to maintain uniform light intensity throughout the ventilated space, or to maintain a constancy of exposure in so mobile a medium.

The first step in the solution of the time-space inter-relationship was to develop means for determining the rate at which some test organism is killed at known distances from a given light. This cannot be done simply by exposing a quartz flask of air at some given distance from the light, because of the large volumes of air involved and the high cost of quartz. It was, however, possible to devise a dynamic method for exposing flowing air at predetermined distances from a given light for periods determined by the velocity of flow.

The number of organisms killed in moving from point to point toward a light can be determined. The integrated products of the times of exposure multiplied by the distances from the light then bears a simple relationship to the distances of the two sampling points from the light, by means of which the killing power constant of that light can be readily computed.

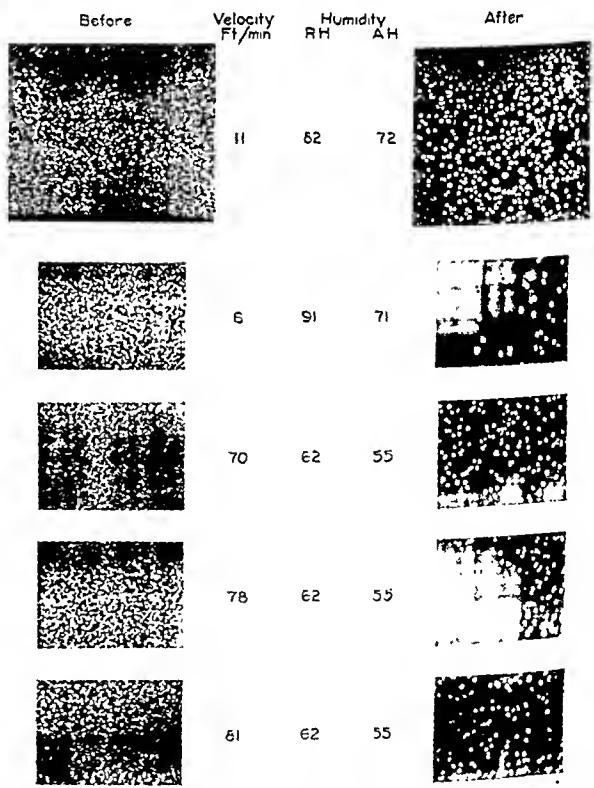

Fig. 4.—Bactericidal action of ultraviolet radiation on *B. coli* in air at different humidities. Passing light.

By sampling simultaneously at points upstream and downstream from the light, marked reduction in this tunnel was observed at velocities up to 222 feet per minute. The bactericidal effects in passing the light at six widely differing velocities under otherwise comparable conditions are illustrated in figure 3. More

23. Whisler, Benjamin: Unpublished thesis. Harvard University, 1936.

than half the bacteria were killed at velocities of 222 feet per minute, and yet some survived passage at a velocity of 30 feet per minute, which represents more than seven times the exposure.

Assuming the bacterial death rate to be proportional to the light intensity as given by the inverse square law for each point in space, it is possible to set up and integrate equations that can be tested by these experimental conditions.<sup>24</sup>

The values of  $KI_0 \equiv K_0$ , as given by these equations, with *B. coli* as the test organism, were found over the wide range of time-space variations, indicated by these tunnel experiments, to be constant within the errors expected from so simple an arrangement. Whisler's intensive studies with more refined apparatus confirmed the substantial validity of the assumptions and the practical applicability of the formulation. The values thus obtained for the constant  $K_0$  justify the initial assumption, which may now be modified and stated in the following form:

The total number of given organisms killed by a given light is proportional to the total quantity of light energy intercepted by the living organisms and approaches a maximum as the product of time and intensity for each approaches uniformity.<sup>20</sup>

Humidity: For constant atmospheric conditions the value of  $I_0$  in these equations defines the killing power of a given source against organisms having a vulnerability defined by  $K$ . The results illustrated in figure 3 were thus obtained under relatively uniform humidity. Comparison with the results given in figure 4 reveals amazing differences in bactericidal effect with different humidities. The results obtained at flows of 65 feet per minute shown in figure 3 are strikingly similar to the results shown in figure 4 for flows of only 6 feet per minute. This tenfold difference in killing power is the result of a difference in relative humidity between 45 and 90 per cent.

The numerical values of  $\log \frac{N_0}{N_t}$  obtained in the tunnel experiments are plotted on figure 5 against the reciprocal of the velocity in conformity with the equations. It is seen from this chart that the results fall into two classes, each class represented by a straight line as would occur if  $K$  were constant for the class. The angle between the lines indicates a wide difference between the value for  $K$  for each class and it is seen that this difference corresponds to a difference in relative humidity, the killing power at low humidities being approximately ten times those obtained at high humidities. Since the inverse square law has been found to hold with high humidities as well as low humidities, the reduction in killing power appears to be due to interference with the bactericidal reaction on the bacteria.

24. The formulation for simple physical combinations are summarized: If  $N_0$  = number of organisms before and  $N_t$  = number of organisms after irradiation by light of lethal intensity  $I$  for time  $t$ , then  $\log_e \frac{N_t}{N_0} = -KI$ ; and at  $r$  distance from a source  $I_0 = \frac{-KI_0 t}{r^2}$ ; and in a sphere of  $R$  radius (source at center), maximum  $= \frac{-3KI_0 t}{R^2}$  for infinite mixing of air, and minimum  $= \frac{-1.2KI_0 t}{R^2}$  for zero mixing of air; and approaching a source at velocity  $v$  from  $+\infty$  to  $r$  distance from source,  $= \frac{-KI_0}{v \cdot r}$ ; and passing the source (from  $+\infty$  to  $-\infty$ ) on a straight line  $r$  distance from source,  $= \frac{-\pi KI_0}{v \cdot r}$ , and for a cylinder of  $R$  radius with source in axis (from  $+\infty$  to  $-\infty$ ), maximum  $= \frac{-2\pi KI_0}{v \cdot R}$  for infinite turbulence, and minimum  $= \frac{-1.24\pi KI_0}{v \cdot R}$  for stream line flow.

The results of the more intensive study by Whisler clearly corroborate the relation between the vulnerability of *B. coli* and relative humidity. The values of  $K_0 \equiv KI_0$  drop precipitately between relative humidities of 55 per cent and 65 per cent, above and below which the change is gradual, the values approaching constancy.

Obviously, humidity becomes a basic factor governing the bactericidal effect of ultraviolet radiations on bacteria suspended in air, the killing power for low humidities being manyfold that observed at higher humidities.

Spectral Range: Gates<sup>25</sup> has thoroughly investigated the lethal action of different wavelengths of light on bacteria smeared on agar plates. His conclusion that waves longer than 300 millimicrons are relatively ineffective has been confirmed for air suspensions of bacteria by filtering out these shorter waves. His con-

Fig. 5.—Effect of humidity on death of *B. coli* passing ultraviolet rays in tunnel.

clusion that the maximum effect lies in a zone midway between 200 and 300 millimicrons would conform to the values of  $KI_0$  obtained by lamps emitting different spectral ranges. The most efficient source among several types tested proved to be a 48 inch quartz Geisler mercury tube<sup>26</sup> emitting 90 per cent of its radiation as a wavelength of 254 millimicrons. Only 12 inches of a double arc gave a value for  $KI_0$  of 910, at a relative humidity of 42 per cent, when tested against *B. coli*. Since this lamp consumes about 35 watts, the  $KI_0$  approximates 50 per watt. If this value is applied in the preceding equations, it is seen that less than one colon bacillus per thousand suspended in several thousand feet of air would remain after irradiation with this light.

Those ultraviolet ray sources which emit the largest proportion of radiant energy midway between 200 and 300 millimicrons are most efficient in destroying micro-organisms suspended in air.

26. Kindly lent by the Hanovia Chemical Manufacturing Company

**Biologic Factors.**—The bactericidal ranges of commercial ultraviolet lamps seemed to warrant experiments looking toward their practical application in sanitary air control. A therapeutic lamp was therefore set up in a clinic of the Children's Hospital, where the atmosphere had been found to build up a relatively high bacterial concentration during hours of active service. Preliminary tests, however, did not give the expected results. The lamp was found by test to be adequate and also proved in the clinic room to be effective against *B. coli*. If the presence of more resistant organisms was the explanation of these disappointing results, an important question was raised, since there is no hygienic significance in the elimination of *B. coli* from air. This study was therefore temporarily put aside until further information regarding the relative vulnerability of significant organisms to ultraviolet radiation could be

be rubbed off, and spread through the air to other surfaces. The relative coarseness of the suspended particles, as compared to droplet nuclei, was indicated by the ratio of bacterial counts on centrifuge tubes and on Petri plates, which was intermediate between the ratios found in the humidified weaving rooms and the dusty carding rooms of cotton mills.

The organisms first subjected to test in the experimental tank were the staphylococci and sarcinae isolated from the tubes taken at the Children's Hospital. The staphylococci were considerably more resistant than *B. coli*, sarcinae considerably more resistant than staphylococci. Alpha streptococci, on the other hand, were comparable in their vulnerability to *B. coli*.

The fact that the less vulnerable organisms were those which normally grow in masses and are separated only with difficulty suggested that their apparent resistance to light, as compared with those which separate naturally into individual unit cells, was due to this grouping. Streptococci, which divide in parallel planes, forming chains which are readily broken up, were comparable in their vulnerability to *B. coli*; staphylococci, which divide irregularly in more than one plane, resulting in cohesive grapelike clusters, were more resistant; while sarcinae, which divide in three planes at right angles to one another, forming packets with a minimum of eight cells, were still more resistant. To determine whether the manner in which organisms naturally group themselves was a prime factor in their varying resistance, cultures were grown in a revolving flask with suitable culture medium barely covering a layer of glass beads. Grinding during growth in this tiny ball mill, followed by prolonged centrifugating, provided a technic whereby suspensions consisting largely, though never entirely, of individual unit cells of streptococci and staphylococci could be tested against ultraviolet rays. Sarcinae, on the other hand, could not be broken down further than to the packet of eight cells, which seemed to constitute the basic unit.

In table 2 is given the vulnerability constant *K* for four organisms grown in the revolver, with *B. coli* for comparison. The differences in vulnerability between unit cells of streptococci and staphylococci, produced by this technic, and the naturally single cells of *B. coli* are within the limits of experimental error. The vulnerability constant for sarcinae, however, differs markedly from those for the other organisms. Presumably each of the eight cells in a packet is sufficient for reproduction, and it would be necessary to kill all eight to prevent a colony developing from a suspended packet.

The mathematical formulation employed in the derivation of the constant *K* for single cells must obviously be modified before application to multicellular groups of organisms. Under the conditions of the test, thirteen times as much light was required to destroy all eight of the cells grouped in a sarcinae packet as was required to kill each colon bacillus dispersed individually. This would conform to the assumption that the vulnerability of individual cells is likewise similar to that of the other organisms given in the table. A progressive increase in the vulnerability constant *K* during the course of the tests was observed for those organisms which tend to form clusters, but not for *B. coli*, as would be expected if the number of cells in the clusters is being reduced by a natural death rate. The implied assumption that only one light unit is required to destroy one life unit, which underlies the mathematical formulation, thus appears to be satisfied.

TABLE 2.—Relative Vulnerability to Ultraviolet Radiation of Individual Cells of Various Cocci Suspended in Air (*B. coli* 1.00)

Organism	Number of Runs	Vulnerability	
		Constant	<i>K</i>
<i>B. coli</i> .....	20	1.00	
<i>Streptococcus viridans</i> .....	5	1.05	±.07
<i>Staphylococcus albus</i> .....	5	1.18	±.07
<i>Staphylococcus aureus</i> .....	7	1.21	±.20
<i>Sarcina lutea</i> *.....	3	0.85	±.02

\* The chance that all eight cells of a packet will be killed is the eighth power of the chance that an individual cell in a packet will be killed. If one half of the cells in a packet lie in the shadow of the other half, and if the packet turns in such a manner that each cell shares equally the light and shadow, the chance of a cell in a packet being killed is one-half the chance when the cells are so distributed in space that no cell eclipses another. From the determination of the vulnerability of packets of sarcinae (0.053 when 66 per cent survived), the vulnerability constant of the individual sarcina cell has been computed as 0.85, if *B. coli* is given a value of one. Since, in the determination, packets flowed in a smooth stream past the light source in less than two seconds, it is doubtful whether each cell shared equally in light and shadow. Since exposure to equal quantities of light is the condition of maximum killing, the vulnerability of sarcina cells would be greater than is indicated by this computed value. The fact that doubling the intensity of the light increased the proportion of packets killed by only 7 per cent would indicate that a constant proportion of cells were thus protected from the light, owing to a constant condition of flow, which was not affected by changes in light intensity. From the figures, it would appear that more than half of the packets survived because of protected cells, and the vulnerability constant of individual sarcina cells is greater than one. The importance of illuminating particles on various sides becomes apparent.

ascertained. The equipment previously developed for determining the viability of droplet nuclei infection was therefore adapted to the study of the biologic factors bearing on the germicidal effect of ultraviolet radiation. Samples of air were withdrawn from the tank through sianized tubes to two Wells air centrifuges. One branch led directly to a centrifuge; the other branch included a small chamber enclosing a quartz Geisler mercury tube, by means of which the air passing to the second centrifuge could be irradiated with ultraviolet light. Organisms in the tubes taken at the Children's Hospital both before and after irradiation of the air were observed to be predominantly sarcinae and staphylococci, owing probably to the nature of the activities of that particular clinic. These organisms are characteristic of the skin and were raised into the air by the dressing and undressing of the patients, together with the treatments given, which consisted largely of massage, manipulative exercises, and so on. These organisms typically grow in clusters and are thrown into the air in masses, which may be a natural provision for the survival of organisms adapted to grow on surfaces,

Cell units of the organisms so far tested, therefore, have proved to be equally vulnerable to ultraviolet radiation.

The study of the biologic factors underlying the vulnerability constants is far from complete. Such factors as capsule formation, spores and pigment remain to be explored. Ultimately the vulnerability constants of pathogens will be independently determined. The fact shown in table 2, that *Staphylococcus aureus* and *Staphylococcus albus* do not, in spite of the difference in pigment, differ markedly, suggests that the latter factor is not of the prime importance that might be imagined. There has not been enough work to indicate that more resistant organisms are not common. There is, however, sufficient evidence to indicate that *B. coli* is not peculiar in its susceptibility.

In the practical application of ultraviolet radiation it becomes evident that a distinction must be made between clumps and individual organisms, between dust and droplet nuclei. Air purification methods that depend on filtration or sedimentation may be more effective against dust, and ultraviolet rays may be more effective against nuclei, the two being complementary and therefore effectively combined. Likewise, methods that are effective in testing for one type of suspended organism may be inappropriate for testing the efficiency of purification devices against the other type.

**Virucidal Action of Light:**<sup>11</sup> The persistent belief that air may transmit certain virus diseases made it important to determine whether bactericidal light would also destroy air suspensions of virus. Into the air of the tank were atomized the filtrates of lung emulsions of ferrets made ill with the Puerto Rico 8 strain of influenza virus. Simultaneous sampling under identical conditions of air as it came from the tank and after ultraviolet irradiation indicated a definite virucidal action of the rays. In two tests the ferrets that were inoculated with material recovered from unirradiated tank air suffered a typical attack of influenza, which was confirmed by virus neutralization tests. The ferrets that received material simultaneously recovered from the air of the tank under identical conditions, except for irradiation of the air, failed to show any symptoms of influenza, and virus neutralization tests subsequently showed no development of immunity.

The infectivity for ferrets of air suspensions of the Puerto Rico 8 strain of influenza virus was destroyed by ultraviolet radiation.

#### APPLICATION OF SANITARY AIR CONTROL

The question of air-borne infection will not be definitely answered until common air supplies are rendered free from nasopharyngeal contamination, just as endemic water-borne intestinal disease became apparent only with change from polluted to pure water supplies.

A solid foundation for sanitary air analysis has been developed, by which the purity of air can be determined, air contamination interpreted, and the efficiency of air purification processes tested. The practical effectiveness of certain devices that can be applied to the bacterial purification of air has been demonstrated. Others<sup>22</sup> have reported beneficial results following control of the bacterial content of the air of operating rooms. The experimental application of sanitary air control in hospitals, schools and other gathering places is indicated.

## Clinical Notes, Suggestions and New Instruments

### ANTERIOR LENTICONUS

E. C. MOULTON, M.D., FORT SMITH, ARK.

Anterior lenticonus is such an extremely rare condition that this case is presented briefly for consideration. All literature to date reveals only ten undoubted cases. Dr. Benjamin Rones reviewed these cases before this section in 1934. The case here presented is offered as the eleventh true type of anterior lenticonus.

Fig. 1.—Right eye showing semidiagrammatically the extent and relative size of the cone.

Fig. 2.—Same case as in figure 1 showing left eye, on which an optical iridectomy had been done.

#### REPORT OF CASE

S. W. H., a man, aged 33, came under observation in March 1927. Since the age of 17 he had been aware of poor vision, causing him to give up boxing and to be refused enlistment in the army. As a furnace builder in a glass factory he was considerably handicapped. Vision in a darkened room was:

Right 20/100 + 1.00 = 20/70  
Left 20/70 + 1.00 = 20/50

When the refraction room was illuminated vision became reduced to 10/200 and did not admit of any improvement, this

Read before the Section on Ophthalmology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

change, of course, resulting from the alteration in the size of the pupil.

With the ophthalmoscope the usually described "oil drop" in the center of the pupil was noticed, and then by use of the loupe and focal light the anterior lenticonus could be detected. Under atropine the fundus could be seen nicely through the peripheral emmetropic lens substance and also a clear view was obtained through the apex of the cone with a minus 20.00

Fig. 3.—Slit lamp appearance with broad beam of light showing corneal parallelepiped and the beam of light traversing the lens with the cone on its anterior surface.

lens in the sight hole. With the exception of the lenticular defect in each eye all the media and fundus were quite normal. In a few days when the effect of the mydriatic had worn off and the pupil, in myosis, was again the size of the base of the cone, the patient reported and requested more atropine in his eyes. Reluctantly it was given him for personal use. He used it continuously against my advice, alternating eyes a week at a time. Finally in 1934 he was persuaded of the danger of this practice and submitted to operation.

Fig. 4.—Optical section with very narrow light beam and full illumination. Only the anterior band of the lens and the anterior band of disjunction are involved, all the other zones of discontinuity being quite normal.

An iridectomy was done in the lower nasal quadrant of the left eye with resulting 20/50 vision and discontinuance of atropine. At no time have glasses been of comfort.

The microscopic examination of the lens with the slit lamp in January 1936 was most striking. With a broad beam of light the cone was clearly seen but it was with the very narrow beam and full illumination that the details in optical section

are so instructive. The results are quite parallel to the reports of Kienecker<sup>1</sup> and Feigenbaum,<sup>2</sup> which are the only other two cases observed with the slit lamp. In this case only two zones of discontinuity are involved, namely the anterior band of the lens and the anterior band of disjunction. There are no accessory bands. These two bands bend forward over the clear underlying contents of the conus without alteration in their parallelism or change in thickness of either zone. The zones defining the adult nucleus and the fetal nucleus are quite normal, as are all the posterior bands. On the apex of each cone and situated just beneath the intact anterior capsule, are a few very minute and delicate brown granular opacities.

Thus the three cases examined to date with the slit lamp must be of the acquired form of anterior lenticonus, and in this one, as in the other two, it is a question rather of lenticlobus than of lenticonus.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.  
HOWARD A. CARTER, Secretary.

### INTERFERENCE WITH RADIO COMMUNICATION BY THERAPEUTIC EQUIPMENT

H. B. WILLIAMS, M.D., Sc.D.  
NEW YORK

There is hardly a home now which is without a radio-receiving set and hardly an individual who does not understand the meaning of the word "static" as used in connection with radio reception. While relatively little can be done at present to prevent disturbance by electrical storms, a great deal of disturbance for which Mother Nature has been blamed has originated in the activities of man. Some of this man-made "static" is unnecessary and most of it can be prevented for a price. Fortunately, in many cases, this price is not prohibitively high.

While the radio in the average home is largely a matter of entertainment and can be dispensed with when necessary, there are other uses, such as communication between ships and shore, aircraft and ground, and the transmission of directional signals, interference with which may easily result in loss of life.

Many of the members of the medical profession will learn with surprise that we have been, unwittingly, responsible for broadcasting a great deal of disturbance of a particularly annoying type. The most prominent offenders in our armamentarium are the various medical and surgical diathermy machines, particularly the new short wave diathermy and artificial fever devices.

Last winter important activities of the Naval Research Laboratory at Washington, D. C., were subjected to interference so serious as to stop the work completely. Eventually, after great trouble and expense, the disturbance was traced to therapeutic equipment. The first disturbing instrument located was a diathermy unit located in a hospital at Cambridge, Mass.

It is common knowledge that broadcasting stations make use of a large aerial structure to facilitate radiation of energy. Without such a structure the disturbance, unless exceptionally intense, is unlikely to be felt at great distances. The apparatus at Cambridge was found to have been so connected to the power supply line that the latter functioned as an antenna

1. Kienecker, R.: *Klin. Monatsbl. f. Augenh.* 82: 55 (Jan. 28) 1929.  
2. Feigenbaum, A.: *Folia ophth. orient.* 1: 103 (Nov.) 1932.

and enabled this small apparatus to broadcast a "sky wave" of considerable intensity. The insertion of a suitable electric filter between the apparatus and the power line was all that was necessary to stop most of the trouble. It is of interest to know that this equipment was supplied and installed by an electrical manufacturer who also supplies vast quantities of radio equipment and is vitally interested in avoidance of interference. In view of this I think that the medical profession may be forgiven for the trouble that has occurred in the past; but now that the facts are known every effort should be made to minimize the evil.

It is expected that the Council on Physical Therapy of the American Medical Association will presently alter its requirements for acceptance of electrical equipment such as is known to have caused interference. Manufacturers will be asked to submit evidence that the construction and installation specifications are such as to prevent interference.

Even though an apparatus may not broadcast an intense sky wave, it will, unless properly filtered, cause disturbance of every radio receiving set which derives power from the same line, thus becoming a nuisance even if it escapes being a menace.

It is confidently expected that users of existing equipment purchased from reliable manufacturers will be able to secure from the manufacturers such additional equipment and engineering advice as will make it possible to prevent interference. Any one who has difficulty in obtaining the desired information or equipment is invited to communicate with the Secretary of the Council on Physical Therapy of the American Medical Association.

It is imperative that the medical profession and the manufacturers of electrical equipment for the profession take prompt steps to abate this nuisance, as otherwise it is certain that relief through legislation will be requested. This is liable to bring undesirable restrictions and will probably be entirely unnecessary if suitable action is initiated by the profession itself.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

#### SEXTON BRAND BARTLETT PEARS, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned pears packed in juice.

*Manufacture.*—Bartlett pears harvested green are stored to reach proper degree of ripeness, graded, mechanically peeled, cut, stemmed, inspected, brined, rinsed and placed in cans. The cans are automatically filled with fruit juice, exhausted, sealed and processed at 100 C.

*Analysis* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 87.0%, total solids 13.0%, ash 0.3%, fat (ether extract) 0.1%, protein ( $N \times 6.25$ ) 0.2%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 11.9%.

*Calories.*—0.49 per gram; 14 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

- (a) OUR PRIDE BRAND CRYSTAL WHITE SYRUP
- (b) OUR PRIDE BRAND GOLDEN TABLE SYRUP

*Distributor.*—Meyer Schmid Grocer Company, St. Louis.

*Packer.*—Union Starch and Refining Company, Granite City, Ill.

*Description.*—(a) A table syrup; corn syrup sweetened with sucrose; flavored with vanilla extract—the same as Pennant Crystal White Syrup (THE JOURNAL, Jan. 30, 1932, p. 403). (b) A table syrup; corn syrup flavored with refiners' syrup—the same as Pennant Golden Table Syrup (THE JOURNAL, Jan. 30, 1932, p. 403).

*Claims of Manufacturer.*—For table use and as a carbohydrate supplement for milk modification in infant feeding.

#### SEXTON BRAND APPLE SAUCE, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned apple sauce prepared from peeled and cored apples.

*Manufacture.*—Blended varieties of western New York apples, tree ripened, are hand picked, spray washed, mechanically peeled and cored, inspected, washed in salt water, and cooked to the proper degree. Seeds and fibrous parts are removed by pulping machine and the apple sauce is hermetically sealed and processed.

*Analyses* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 87.7%, total solids 12.3%, ash 0.24%, fat (ether extract) 0.2%, protein ( $N \times 6.25$ ) 0.2%, crude fiber 0.46%, carbohydrates other than crude fiber (by difference) 10.2%.

*Calories.*—0.43 per gram; 12 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

#### GOLDEN DRIP BRAND SYRUP SILVER DRIP BRAND CRYSTAL WHITE SYRUP

*Distributor.*—Empire Distributing Co., St. Louis.

*Manufacturer.*—Union Starch & Refining Co., Granite City, Ill.

*Description.*—1. A table syrup; corn syrup flavored with refiners' syrup; the same as Pennant Golden Table Syrup (THE JOURNAL, Jan. 30, 1932, p. 403). 2. A table syrup; corn syrup sweetened with sucrose; flavored with vanilla extract; the same as Pennant Crystal White Syrup (THE JOURNAL, Jan. 30, 1932, p. 402).

#### APOLLO BRAND TOMATO JUICE

*Distributor.*—Halpen-Green Company, Philadelphia.

*Packer.*—Vincennes Packing Corporation, Vincennes, Ind.

*Description.*—Pasteurized tomato juice with added salt; retains in high degree the vitamin content of the raw juice. (The same as Alice of Old Vincennes Tomato Juice, THE JOURNAL, Feb. 20, 1932, p. 640.)

#### GROSSE POINTE BRAND FANCY CRUSHED HAWAIIAN PINEAPPLE

*Distributor.*—R. Schayowitz & Sons, Detroit.

*Packer.*—Hawaiian Pineapple Company, San Francisco.

*Description.*—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole canned pineapple (THE JOURNAL, April 8, 1933, p. 1106).

#### HEART OF AMERICA BRAND TOMATO JUICE

*Distributor.*—Christopher Sales Company, Kansas City, Kan.

*Packer.*—Vincennes Packing Corporation, Vincennes, Ind.

*Description.*—Pasteurized tomato juice with added salt; retains in high degree the vitamin content of the raw juice; the same as Alice of Old Vincennes Tomato Juice (THE JOURNAL, Feb. 20, 1932, p. 640).

## PHYSICIANS AND OLD AGE PENSION TAXES UNDER THE SOCIAL SECURITY ACT

Preliminary procedures are under way to make effective the old age benefit provisions of the Social Security Act. The regulations that have been promulgated by the Bureau of Internal Revenue looking toward the assembly of the mass of detailed data with respect to the employers and employees from whom the taxes are to be collected are of immediate interest to physicians.

Each person who on November 16 was the employer of one or more persons, subject to the exceptions noted, must have reported that fact prior to November 21 to the postmaster from whose post office the employer obtained his office or business mail. He must also have made application on form SS-4 for the assignment of a number—an "identification number" to be used for identification purposes in connection with the collection of taxes under the act. Physicians who were employers on the date named were required to comply with this requirement. If they failed to do so they should now communicate with their local postmasters for instructions as to how to proceed to make the delayed application. A physician who became an employer after November 16 must also apply for an identification number within a period of thirty days after the relationship of employer and employee is established. This application, the regulations provide, must be made to the field office of the Social Security Board in the area in which the office of the physician is situated or, in the absence of such field office, to the Social Security Board at Washington, D. C.

Persons who were employees on November 24 are likewise required to obtain numbers, called "account numbers," by filing application on form SS-5, on or before December 5, with the local postmaster. Persons becoming employees after November 24 must also file application for numbers thirty days after the employment begins. While physicians generally are considered, under the regulations, as independent contractors and consequently not subject to the taxes imposed on employees, if physicians are employed on a full time

or part time salary basis they are apparently to be considered as employees. Such physicians must file application for "account numbers" on form SS-5. As employees they are subject to the tax on employees, and their employers must pay the employer's tax with respect to them.

Certain employments do not come within the old age benefit provisions of the Social Security Act. Among the exceptions are agricultural labor, domestic service in a private home, casual labor not in the course of the employer's trade or business, service performed by an individual who has attained the age of 65, service performed in the employ of the United States or of any state or subdivision or instrumentality of either, and service performed in the employ of a corporation, community chest, fund or foundation organized and operated exclusively for religious, charitable, scientific, literary or educational purposes, or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual. Physicians who employ only persons embraced within these excepted employments or who are themselves engaged in such excepted services are not required to make application for identification or account numbers.

Employers' and employees' taxes will be collected by means of monthly returns to be filed by employers, who not only must pay to the local collector of internal revenue the tax imposed on employers but also must deduct from the wages of their employees the employee's tax and transmit that also to the collector. The first returns will be due not later than March 1, 1937, covering wages paid for services rendered during the month of January. The regulations that have been promulgated cover in detail the records that must be kept by employers, the method of executing returns, the information they must contain and other matters relating to the tax. Physicians should promptly familiarize themselves with all the requirements, so that as much confusion as possible may be avoided. THE JOURNAL will from time to time offer suggestions to aid physicians in meeting the requirements of the act.

## MYASTHENIA GRAVIS

Myasthenia gravis was first described by Willis<sup>1</sup> in the seventeenth century. For years it was considered a neurologic disorder even though investigators did not find any constant or characteristic lesion of the central or peripheral nervous system. Jolly<sup>2</sup> in 1895 suggested that the disease might be primarily one of the muscles. Later the muscular localization of this disorder was more firmly established by Buzzard's<sup>3</sup> demonstration that lymphocytic infiltration was more or less consis-

1. Willis, quoted by Guthrie, L. G.: "Myasthenia Gravis" in the Seventeenth Century, *Lancet* 1:330 (Jan. 31) 1903.

2. Jolly, F.: I. Ueber Myasthenia gravis pseudoparalytica, *Berl. Klin. Wchschr.* 32:1 (Jan. 7) 1895.

3. Buzzard, E. F.: Myasthenia Gravis, *Tr. Path. Soc. London* 56:355, 1905.

tently a pathologic characteristic of the muscle fibers of patients who had the disease. These fundamental observations impelled investigators in the field definitely to shift their interest from the nervous to the muscular system. Meanwhile hyperplasia of the thymus, in association with myasthenia gravis, was noted by Oppenheim<sup>4</sup> in 1899. Subsequently hyperplasia of the thymus was found in nearly half of the cases in which necropsy was performed. This was sufficient to cause many investigators to consider such enlargements as of etiologic significance. Nearly every other ductless gland also has been incriminated, but there is a distinct lack of any substantial evidence of their participation in the syndrome.

Finally it was recognized that in this disease some phase of muscle metabolism was disturbed. The finding of creatine in the urine of a few patients who had myasthenia gravis, coupled with the known importance of phosphocreatine in muscle metabolism, stimulated interest in the possibility that the disease was primarily one of intermediary muscle metabolism. Evidence of a specific disturbance of metabolism, however, has not been obtained by the methods of investigation at present available, as has been shown by the comprehensive chemical studies by Boothby and his co-workers.<sup>5</sup> Creatinuria was observed in only seven of their thirty cases; however, after the daily administration of aminoacetic acid was started there developed a definite increase in the amount of creatine excreted by those who had a previous creatinuria; and a creatinuria developed to a greater or less degree in those who did not previously excrete creatine. A similar increase in creatinuria also occurs in most normal persons after the ingestion of aminoacetic acid. Some investigators have conjectured that the site of the process responsible for the fatigability characteristic of the disease is at the myoneural junction. Most, however, are still satisfied that the disturbance of function is within the muscle fiber; they leave the mechanism of the disturbance and its exact localization within the muscle fiber in the realm of speculation.

Associated closely with the advancing knowledge of myasthenia gravis has been the study of the chemical mediation of nerve impulses. Recent research<sup>6</sup> indicates that acetylcholine is liberated on stimulation of motor nerves to voluntary, striated muscle. It is further recognized that physostigmine and prostigmin<sup>7</sup> probably prevent destruction of acetylcholine by inhibition

of the normal blood choline esterase. Concentration of this esterase has been reported by Stedman<sup>8</sup> to be low in one case of myasthenia gravis. Potassium chloride,<sup>9</sup> when injected into the arteries of cats, will cause release of acetylcholine from tissues of which the innervation is cholinergic. These interesting observations merit consideration in view of their obvious importance in interpretation of the pathogenesis of the disease. However, to attempt at present a deduction from the information available might result in many fallacious concepts. This most recent work obviously does not tell the whole story. Boothby<sup>10</sup> has aptly stated that investigators are still ignorant of the cause of the disturbance in the contracting mechanism, which is an important feature of myasthenia gravis.

Many investigators have noted the relationship between myasthenia gravis and infection, especially infection of the upper part of the respiratory tract, and some of them have suggested, without direct evidence, that a toxin, probably of microbic origin, is the agent responsible for some type of chemical upset causing the characteristic fatigability. In a recent study Butt<sup>11</sup> has demonstrated gram-positive diplococci within or between the muscle fibers in some of the sections of muscle in seven cases of myasthenia gravis. Norris<sup>12</sup> also has demonstrated micro-organisms in the muscles of a patient who had this disease; but since he found them also in the muscles of a patient who had Addison's disease and in those of normal controls he was not inclined to consider their presence as significant. Rosenow and Heilman<sup>13</sup> have successfully taken cultures and identified streptococci from patients who had the disease and have produced the clinical and pathologic picture in animals by inoculating them with these organisms. It remains for future investigations to determine whether these organisms are the agents responsible for this syndrome.

Some of the most important recent contributions in the study of myasthenia gravis have been in treatment. The beneficial effect of ephedrine was demonstrated by Edgeworth<sup>14</sup> in 1930, and the value of aminoacetic acid was pointed out simultaneously by Remen<sup>15</sup> and by Boothby<sup>16</sup> in 1932 following the report of Thomas,

7. Prostigmin is the dimethyl carbamic ester of hydroxyphenyltrimethyl ammonium methylsulfate.

Milhorat and Techner<sup>17</sup> on the improvement in fatigability following the administration of aminoacetic acid to a patient who had progressive muscular dystrophy. Knowledge of the effects of these substances has almost completely changed the course of treatment and the prognosis. In addition, the fact that physostigmine,<sup>18</sup> prostigmin<sup>19</sup> and potassium chloride<sup>20</sup> exert favorable effects on patients who have myasthenia gravis have stimulated a great amount of interest in treatment of the disease.

Boothby<sup>21</sup> has emphasized the fact that the disease is of long duration and that no single therapeutic procedure or any one drug cures the disease. Therefore the patient must be educated to avoid so far as possible the dangerous complications of myasthenia gravis; also all available therapeutic procedures must be utilized to decrease the characteristic fatigability. Of the eighty-two patients treated by Boothby, fifty are now working either full time or part time and although such results, in such a large series, are unusually favorable, there is still urgent need for continuation of carefully conducted and controlled studies of this disease.

## Current Comment

### INFLUENZA IN THE UNITED STATES

During eleven of the seventeen years since the summer of 1919, recognizable outbreaks of influenza have occurred. Since one of the chief characteristics of an influenza epidemic is the suddenness of its outbreak and the rapidity with which it spreads over a large area, any unusual increase in the number of reported cases of influenza in one locality is usually viewed with alarm. Miss Gover<sup>1</sup> has recently studied the epidemic of the past winter in the West South Central section of the country and elsewhere with a view to determining whether any greater outbreak is foreshadowed by the existing situation. Throughout the period of the epidemic of 1936 California was reporting more than the average number of cases of influenza for preceding years, but the curve of mortality for the Pacific section was only slightly higher than normal. By May 2 the California cases had

dropped to normal. During the five weeks from May 31 to July 4 California reported 2,177 cases of influenza as against an expectancy of 124, or an excess of 2,053 cases. A summer rise, such as this, is unusual, but there was no parallel rise in mortality, and since July 4 through September 19 California as well as the Pacific area has been reporting only an average number of cases for that season of the year. The author concludes, therefore, that although an epidemic of influenza may occur this winter, the recent mortality from influenza does not indicate that such an epidemic is in progress in any section of the country at the present time.

### THE ARMY MEDICAL LIBRARY—ONE-HUNDREDTH ANNIVERSARY

The one-hundredth anniversary of the Army Medical Library was celebrated in Washington November 16 with appropriate ceremony. High tribute was paid in a message by President Roosevelt. The librarian, Col. Harold W. Jones, reviewed its development and Surgeon General Reynolds introduced the centennial speaker, Sir Humphry Davy Rolleston, Bart., who had come from England especially for this occasion. In a scholarly address he reviewed the history of medical museums and libraries and the biographies of the great bibliographers—Billings, Fletcher and Garrison—who had been associated with the Army Medical Library in its growth. The occasion served incidentally to call attention to the pressing need for new quarters, the invaluable collection of books and documents being housed in a half-century old, non-fireproofed structure. THE JOURNAL again felicitates the Library on its marvelous record and expresses the wish that its hope for a new and suitable home may soon be realized.

### IN HONOR OF DR. HUGH TALBOT PATRICK

The issue of the *Archives of Neurology and Psychiatry* for November 1936, which has just come from the press, is a special number dedicated to Dr. Hugh Talbot Patrick by his pupils. It contains in addition to notes of appreciation by Drs. Peter Bassoe, Chicago, Bernard Sachs, New York, and Professeur Georges Guillain, Paris, contributions on neurologic topics by these writers and many others who have from time to time been associated with Dr. Patrick in his work. To Dr. Hugh T. Patrick particularly must be assigned the credit for the initiation of the *Archives of Neurology and Psychiatry* as a publication in this special field. Dr. Sachs well states that this publication has done much to place American neurology and psychiatry on the highest scientific level. It has reflected constantly the progress of American medicine in this field. In listing the contributions of Dr. Patrick, special mention is given to his articles on arteriosclerosis of the nervous system, chronic progressive hemiplegia, the motor neuron in practical diagnosis, the proper care and treatment of the patient with epilepsy, syphilis of the nervous system, and the factor of fear in nervous diseases. More recently a number of excellent contributions have indicated his interest in biography and in the historical

aspects of neurology. The dedication of such volumes to men of leadership who have contributed as greatly as has Dr. Hugh T. Patrick toward medical advancement is a commendable gesture in a too careless and hastening age.

## Medical Economics

### THE NATURE OF PANEL PRACTICE IN ENGLAND

#### Some Evidence from the Pages of the British Medical Journal

A series of letters from physicians in the correspondence department of the *British Medical Journal* in recent months indicates that the physicians practicing under the panel system are by no means wholly satisfied with the character of service they are required to give. The letter that started the trouble was from F. S. Taylor-Thomas,<sup>1</sup> who wrote from Australia and says:

My interpretation of the statement is that panel practice in action tends to produce the following:

Patient (entering consulting room, and taking seat on chair) "I want somethin' for this wheezin' on my chest, Doctor. I've had it for a week now. Cough at night somthin' awful."

Doctor: "Very well, take off your things and I'll examine your chest."

Patient: "Oh, never mind that, Doctor! Just give me a hottle of cough mixture—some of that black stuff—and I'll be all right. I just called in as I was passin' up the street and thought I'd better get something before it gets worse."

Doctor (glancing in the waiting room a crowd of other patients who just called in as they were "passin' up the street"): "Very well. Here you are." (Hands him prescription for mist. tussis, fishes out his panel card, enters date, diagnosis, treatment, etc., "shoo's" him out to make way for another who wants something for his rheumatiz in the shoulder—and so the process is repeated.)

Well, isn't that mechanization? Is that all an M.B., B.S. or M.R.C.P. has to do? Has he any chance, or is he allowed to do much, in the ordinary conditions of panel practice? What is the general practitioner in England today but a glorified first-aid man? Quack patients beget quack doctors. It is a question, from the general practitioner's point of view, of getting as many patients as he can on his list and getting the consultations over as fast as he can. Only by such means can a living be made. If the doctor comes across an illness which may interest him, had he the time and were he reasonably paid to treat it, he simply refers the patient to the nearest hospital; insurance committees do not encourage academic excursions by general practitioners. . . . if these people who are patients had only to pay 3d. to see the doctor it would cut down England's drug bill by half.

This letter very clearly started something. The next communication, by a writer under the name of "Juvenis,"<sup>2</sup> and who is apparently a panel practitioner, adds this comment:

I am convinced the majority of panel patients do not get full enough investigation. My surgery hours are cluttered up with people who certainly would not come so often or drink so much medicine if they had to pay even one penny a visit. I cannot do otherwise than rush them through. Those who are obviously ill, or who fail to regain good health after a reasonable lapse of time, are examined more carefully at home or out of surgery hours; but this method is only a makeshift, and I remember with dissatisfaction two carcinomata of the stomach recently diagnosed too late and a latent pulmonary tuberculosis labeled neurotic.

These criticisms brought Alfred Cox,<sup>3</sup> former secretary of the British Medical Association, to the defense with this statement:

I have no doubt that "Juvenis" is sincere in his opinion about the panel system and as to the methods adopted in his practice. But I should be very sorry—and indeed I refuse—to believe that his experience is typical. I have had the good fortune to come in close contact with many busy insurance practitioners who have never had any doubt as to their ability to give their panel patients that which they contract to give—namely, a good general practitioner service.

Dr. Cox gives a statistical study of the services needed in an average panel list of 1,000 and concludes:

I submit that in a well-organized practice every patient needing it could have the thorough examination that he or she ought to have. In times of epidemics, of course, all patients have to take what it is possible to give, but in many cases detailed examination can be deferred for a time.

In a later issue another doctor<sup>4</sup> says:

I have been chairman of the Ross and Cromarty Insurance Committee for several years. I have also been chairman of the Ross and Cromarty Panel Committee for many years, and my index list is one of the largest in this area. I should thus know something of national health insurance practice, its good qualities and its bad qualities.

On the basis of this experience he gives as his opinion: "In the large majority of cases national health insurance practice is of a very high standard, and is not second to the standard of efficiency and rectitude attained by any other profession or business; otherwise, would it for one moment be tolerated by the public?" However, in the same issue Dr. Cox's statistical study is criticized with the following conclusion:

Thus Dr. Cox's own figures suggest that a rush is probably a normal state in general practice for a considerable portion of the year. Most general practitioners are only too aware of this uncomfortable period when patients, panel and private, and their medical attendants suffer from the rush of work. Dr. Cox and the travelers in statistics from the Ministry of Health appear to be uninformed of this rush period, or rather the length of its duration. . . . Again, assuming Dr. Cox's figures to be correct, we find that an attendance on a panel patient is valued at rather less than two shillings. The remedy for this unsatisfactory state of affairs, as was pointed out a fortnight ago, is a revision of fees, both private and panel.

This conclusion as to payments to physicians is confirmed by the statement of another panel practitioner in the same issue who says:

One wonders whether or not Dr. Cox is quite satisfied that the doctors receive an adequate remuneration for this "good general service," as it would appear to be more or less the consensus of opinion that the doctors themselves are not satisfied with their remuneration.

The controversy continues in the issue for October 17. One writer<sup>5</sup> comments:

Many panel patients are irresponsible individuals unfit to enter into a contract with a doctor. These time wasters and the low capitation fee cause some dissatisfaction with the national health insurance service. Is the extent of this dissatisfaction known? Prosperous practitioners occupying prominent positions are unlikely to be dissatisfied, and tend to discourage admission of misgivings by their less fortunate professional brethren. Could not a confidential questionnaire be sent to every panel practitioner so that the truth may be discovered?

"Juvenis" returns to the discussion with a further examination of Dr. Cox's calculations and adds:

A good examination in the surgery takes considerably longer than five minutes. Can any one examine a man for life insurance in five minutes? Moreover, in a practice like this, covering a scattered area of some thirty square miles, fifteen minutes per visit is too low an average of time consumption. Indeed, it is very difficult to find time and energy to read and think about my patients. And even when I do, economic considerations often restrict me to the palliative bottle of medicine. Indeed, I wonder if panel treatment is intended to be more than symptomatic. Of about one hundred formulae for mixtures in the N. H. I. Formulary some fourteen are "cough mixtures"! How many dyspeptics can afford artificial teeth? How can one get a walking caliper for a fractured neck of the femur? How can one treat the host of psychopathic cases when neither the patient's approved society nor the regional medical officer seems to care a jot about treatment?

The editor then states that it is now necessary to "close the correspondence." Quotations from two other physicians, in the same issue, are illuminating as to the attitude of some panel practitioners:

To pretend that panel and well-to-do private patients can be treated identically is to be an ostrich. Unpleasant facts must be faced. Much national health insurance practice consists of futile efforts to adapt the patient to a wrong environment by generous doses of drugs and other poisons. We are in a changing era. Public and private health are slowly merging. Perhaps in the meanwhile the national health insurance practitioner is doing useful work which will be facilitated by the gifts of hypocrisy or self deception.

While it would be unfair to stigmatize the whole profession for the misdeeds of a few of its members, nevertheless there is, I believe, an increasing tendency to practice what has been described in previous letters as mechanized medicine. For this the public are in part to blame. In this aspirin-ridden age pain must be assuaged, discomfort eased forthwith and at any price, and the excuse that one may be trying to cure the case is not always received with becoming gratitude. On the other hand, there is a type of mind—present in all ages of medicine—who will choose the easier path. They have so simplified prescribing as to resemble the famous John Brown of the eighteenth century who divided all the ills of mankind into two categories: (1) the depressed, who required stimulating, and that with alcohol; (2) the overexcited, who must be soothed, and that with laudanum. Few of the modern school, one fears, are as honest as John Brown, who, believing in the efficacy of his own prescription, died of too much alcohol by day and too much laudanum by night!

## Association News

### THE ATLANTIC CITY SESSION

#### Symposium on Heart Disease in the Scientific Exhibit

The Committee on Scientific Exhibit has announced that an exhibit symposium on heart disease will be held at the Atlantic City session, June 7-11, 1937. The symposium, which will cover all phases of the subject, will be presented by various individuals who may have suitable material to offer and the exhibits will be open to awards. Application blanks for space may be obtained from the Director, Scientific Exhibit, 535 North Dearborn Street, Chicago.

### RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced. The announcement cards that were sent out when the program was planned for the Red network can be changed simply by substituting the word "Blue" for "Red" where it occurs.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

- December 1. "Smog." W. W. Bauer, M.D.
- December 8. Heredity and Disease. Morris Fishbein, M.D.
- December 15. Milk. W. W. Bauer, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### CONNECTICUT

**Society News.**—Dr. Richard E. Shope, Princeton, N. J., discussed the "Newer Knowledge of Influenza" before the Yale Medical Society, November 11, in New Haven.

**Dr. Ingraham Leaves State Board of Health.**—Dr. A. Elizabeth Ingraham, since 1923 director of the bureau of child hygiene of the Connecticut State Department of Health, Hartford, has resigned, effective January 1, and, it is reported, will retire from active public health work.

**Graduate Courses.**—The Connecticut State Medical Society and the state department of health opened a course on maternal health at the Windham Community Memorial Hospital, October 6, and the Day-Kimball Hospital, Putnam, October 7. Instructors are Drs. James R. Miller, Hartford, Emerson L. Stone, Abraham Nowell Creadick, Herbert Thoms and Luther K. Musselman, all of New Haven, and Joseph H. Howard, Bridgeport. A course in pediatrics, to be given when the one in obstetrics is completed, is in charge of a committee consisting of Drs. Grover F. Powers, professor of pediatrics, Yale University School of Medicine, chairman; James Harold Root, Waterbury, and Oliver L. Stringfield, Stamford. Instructors will be selected by this committee from the membership of the state medical society. Both courses are being financed by a social security grant.

**Personal.**—Dr. John Homans, clinical professor of surgery, Harvard University Medical School, and surgeon to the Peter Bent Brigham Hospital, Boston, has been appointed visiting professor of surgery at Yale University School of Medicine, New Haven, and surgeon-in-chief of the New Haven Hospital during the period November 1 to June 30, 1937.—Dr. Lewis A. Sexton, for twenty years superintendent of Hartford Hospital, has retired on account of ill health. With the appointment of Dr. Wilmar Mason Allen as director of the hospital, the post of superintendent was discontinued and Dr. Sexton was designated director-emeritus.—Dr. George E. Cogan has been elected president of the Hartford Board of Health, succeeding Dr. Robert V. Boyce, who recently resigned.—Dr. Samuel Green, health officer of Southbury, has presented to the Hartford Board of Health a certificate issued by the Common Council in 1878 appointing his father, the late Dr. George S. Green, a member of the board.

### DELAWARE

**Society News.**—Dr. Manfred S. Guttmacher, Baltimore, discussed "The Relationship of Psychiatry to the Courts" before the New Castle County Medical Society, November 17. Dr. Brooke M. Anspach, Philadelphia, discussed gynecologic conditions, October 20.

### ILLINOIS

**Society News.**—Dr. Joseph Brennemann, Chicago, addressed the Bureau County Medical Society at Princeton, November 10, on "Pneumonia in Childhood."—At a meeting of the Will-Grundy County Medical Society, November 11, Dr. Telf Nelson spoke on the "Management of Bronchial Asthma."—Drs. Ralph A. Reis, Chicago, and Ralph P. Peairs, Normal, discussed gynecology and medical economics, respectively, before the Livingston County Medical Society, November 12.—At a meeting of the Kankakee County Medical Society, November 12, Dr. Margaret M. H. Kunde, Chicago, spoke on "Endocrine Therapy in Menstrual Disturbances."—Dr. John de J. Pemberton, Rochester, Minn., addressed the Peoria City Medical Society, November 10, on surgery of the thyroid gland.

### Chicago

**The Ludvig Hektoen Lecture.**—Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tenn., will deliver the thirteenth Ludvig Hektoen Lecture of the Frank Billings Foundation, January 22. His subject will be "Vaccinia."

**Another Window Exhibit.**—In the lobby window in the Annex Building of Marshall Field and Company is an exhibit on "feet" designed to show that foot disorders are frequently traced to systemic diseases and emphasizing that the family physician should be consulted before any corrective measures are introduced. Models are displayed to show that a shoe should be made to fit the foot rather than the foot to fit the shoe. There is also a model in plaster of the perfect foot of a child. This window has been given to the Chicago Medical Society, free of rental and service charges, for the display of health educational material. The material is prepared by the educational committee of the Illinois State Medical Society.

**Bacteriology Reviewed.**—At a meeting of the Institute of Medicine of Chicago and the Society of Medical History of Chicago, November 24, the following program was presented:

- Dr. Ludvig Hektoen, Notes on the History of Bacteriology in Chicago Prior to the Organization of Bacteriologic Teaching (about 1890).
- Dr. George H. Weaver, The Introduction of Bacteriology into the Medical Curriculum in Chicago.
- Dr. Fred O. Tonney, The Introduction of Bacteriology into the Public Health Service in Chicago.

A paper prepared for the Society of Medical History by Dr. Jacques Holinger, before his death in 1934, was read by title: "An Incident in the Development of Antisepsis and Dr. Henry Banga's Part Therein." Dr. Peter Bassoe will deliver the presidential address before the twenty-first annual dinner and meeting of the Institute of Medicine, December 1, on "A Sketch of the Development of Psychiatry and Neurology in Chicago."

**Beaumont Collection at University of Chicago.**—A collection of papers and personal effects of Dr. William Beaumont has been given to the University of Chicago by the physiologist's grandson, Ethan Allen Beaumont, and his wife, of De Pere, Wis. The collection, consisting of first editions, unpublished letters, a case history, surgical instruments, photographs and a chair presented to the Beaumonts by Robert E. Lee, who once lived with them in St. Louis, was on exhibition at the university library, November 20, together with an oil portrait of Dr. Beaumont lent by Mr. A. C. Denny of Evans-

ton. During the exhibition, addresses were delivered by Robert Maynard Hutchins, president of the university, and Drs. Anton J. Carlson, Arno B. Luckhardt and Selim W. McArthur. The program, sponsored by the Friends of the Library of the University of Chicago, was planned to coincide with the one hundred and fifty-first birthday of Dr. Beaumont, November 21.

**Fund for Study of Hospital Insurance.**—The Rosenwald Fund has given \$100,000 to the American Hospital Association to study and develop voluntary hospital insurance. The program of the association will be projected through a special committee on hospital service with C. Rufus Rorem, Ph.D., as executive director. Other members of the committee are Drs. Basil C. MacLean, Rochester, N. Y., chairman; Sigismund S. Goldwater, New York; Robin C. Buerki, Madison, Wis.; Claude W. Munger, president of the American Hospital Association, and Msgr. Maurice F. Griffin, Cleveland. According to an announcement, one phase of the work will deal with advice and consultation on existing plans and those being formed concerning actuarial data, benefits, method of organization, public relations and annual subscription rates, while a second phase will cover relations of hospital service plans to the medical profession, public welfare activities, state departments of insurance, private insurance companies, hospital administration and hospital accounting.

## IOWA

**Lectures for College Students.**—The speakers' bureau of the Iowa State Medical Society will continue this winter its policy of providing lecturers to colleges in the state. The following program has been tentatively outlined for delivery to the freshmen at Grinnell College: The Body and Its Functions, Medical Science in the Service of Health, Upkeep and Energy Supply, Digestion and Elimination, The Use of Energy in Activities, By-Products of Activity and Energy Renewal, Body Mechanics, Thermal Regulation, Cleanliness and the Appearance, Infection and Resistance, Physical and Chemical Hazards, and Reproduction and Sex.

**Regional Meetings.**—The Southeastern Iowa Medical Society was addressed in Mount Pleasant, October 15, by Drs. Alfred M. Paisley, Keokuk, on eye, ear, nose and throat conditions; Leonard P. Ristine, Mount Pleasant, neurosyphilis; George B. Crow, Burlington, degenerative heart disease, and Mazyck P. Ravenel, Columbia, Mo., immunization against the infectious diseases. Dr. Lonnie A. Coffin, Farmington, delivered his address as president, and Dr. Marcus Pinson Neal, Columbia, the address of the evening on cancer as a preventable disease. Drs. Austin C. Davis and Harry L. Smith, both of Rochester, Minn., addressed the Southwestern Iowa Postgraduate Medical Society in Atlantic, October 9, on "Clinical Significance of Basal Metabolic Rates" and "Attacks of Unconsciousness Associated with Cardiac Diseases" respectively.

**Society News.**—Dr. Karl A. Menninger, Topeka, Kan., discussed "The Problem of Psychological Factors in Medicine" before the Pottawattamie County Medical Society in Council Bluffs, November 16. The society met jointly with the Woodbury County Medical Society, October 12; speakers were Drs. Charles T. Maxwell, "Trends in the Treatment of Diabetes"; Wayland K. Hicks, "Vaginal Ureterolithotomy," and Peirce D. Knott, "Review of 100 Cases of Anterior Poliomyelitis with Special Reference to Therapy." All the speakers are from Sioux City. Dr. Frank A. Evans, Pittsburgh, discussed "The Physiological Background and Treatment of Obesity and Undernutrition" before the Linn County Medical Society, November 19. Dr. Elliott P. Joslin, Boston, addressed the society, October 27, on "The Management of Diabetes." Dr. Benjamin L. Knight, Cedar Rapids, spoke on "Medical Hash and Surgical Tips."

## LOUISIANA

**Society News.**—Dr. Bunnie M. McKoin, Monroe, discussed gonorrhea before the Tri-Parish Medical Society, October 6. The Fourth District Medical Society was addressed, among others, in Shreveport, by Dr. Robert A. Strong, New Orleans, on vomiting in infancy. The Orleans Parish Medical Society and the staff of Charity Hospital held a joint clinical meeting, October 26. The speakers included Drs. Stanford Chaille Jamison on "Toxic Goiter in Six-Year-Old Colored Female"; Frederick F. Boyce, "Primary Streptococcus Peritonitis"; Octave C. Cassegrain and Howard R. Mahorner, "Amebic Hepatic Abscess with Rupture in the Pleural Cavity," and Roy H. Turner, "Syphilis of the Stomach." The society was addressed November 9 by Drs. Leo N. Elson on "Treatment of Trichophytosis Interdigitalis"; Howard R. Mahorner, "Clinical Aspects of Goiter," and Francis E. LeJeune showed color motion pictures of the larynx.

## MASSACHUSETTS

**Cancer Decrease in 1935.**—The deaths from cancer in Massachusetts decreased in 1935, the first time in ten years, according to the *New York Times*. In 1935 the death rate for men was 99.2 and for women 125.2, as compared with 107.2 and 129.4, respectively, in 1934. In 1920 the rate was 84.5 per hundred thousand of population for men and 128.6 for women.

**New Commissioner of Mental Hygiene.**—Dr. David L. Williams, since 1928 a member of the staff of the Veterans' Administration Facility, Bedford, has been appointed state commissioner of mental diseases to succeed Dr. Winfred Overholser. Dr. Williams graduated from Tufts College Medical School in 1906. He is 60 years of age. Dr. Overholser was named assistant commissioner of mental diseases in 1930 and commissioner in 1934.

**Huge X-Ray Machine at Huntington Memorial Hospital.**—A machine capable of producing 1,000,000 volt x-rays is being installed in the Huntington Memorial Hospital, Boston, newspapers report. It generates static electricity and makes possible the treatment of deep-seated malignant growths in the body. Six fast moving vertical belts carry negative electricity to the high voltage terminal in the doughnut-shaped top and on the downward path remove positive electricity from the terminal, depositing it at the grounded base. High speed electrons are thus generated at the terminal and are gathered through a vertical porcelain x-ray tube to be carried downward to a water-cooled gold target. This tube will extend through the floor of the generating room to a room below, where patients will be treated.

**Society News.**—Dr. Merrill Moore, Boston, discussed cases of attempted suicide in a general hospital before the Harvard Medical Society, October 27. The Boston Pathological Society was addressed October 28 by Dr. Ernest A. Codman on "A Study of the Cases in the Registry of Bone Sarcoma of Giant Cell Tumor About the Knee." At the annual meeting of the Massachusetts Society for Mental Hygiene in Boston, November 24, Dr. Helen MacMurchy, Toronto, Ont., spoke on "Mental Hygiene and Child Welfare." Dr. Horace K. Sowles, Boston, will address the Pentucket Association of Physicians, December 10, on "Carcinoma of the Intestines." M. J. Shear, U. S. Public Health Service, addressed the Suffolk District Medical Society, November 18, on "Hydrocarbons and Cancer," and Dr. Joseph C. Aub, Boston, "Cancer Research." At a meeting of the Norfolk District Medical Society in Brighton, October 27, Drs. Thomas R. Healy, Boston, among others, discussed "Radiological Aspects of Yeast Infection of the Lungs"; Charles J. Kickham, Boston, "Recent Advances in the Treatment of Pruritus Vulvae," and John F. Casey, Boston, "Treatment of Pneumonia." Dr. Robert A. Wilson, Brooklyn, discussed "Initiation of Respiration in Asphyxia Neonatorum" before the Obstetrical Society of Boston, October 20.

## MICHIGAN

**Dr. Kellogg Honored.**—A dinner was held in honor of Dr. John Harvey Kellogg, Battle Creek, October 19, marking his completion of sixty years as head of the Battle Creek Sanitarium. Oct. 1, 1876, the year following his graduation from Bellevue Hospital Medical College, Dr. Kellogg took over the management of the Health Reform Institute, now known as the Battle Creek Sanitarium. He is 84 years of age.

**A New Dramatic Broadcast.**—A campaign to eradicate tuberculosis from Detroit was recently launched under the cooperative efforts of the Wayne County Medical Society, the Detroit Tuberculosis Sanatorium Association, the Detroit *News*, Radio Station WWJ, the Detroit Department of Health, and Paul de Kruif. One feature of the program is a weekly broadcast of "Death Fighters," a dramatic story the plot of which has been taken from the records of one of the city's hospitals. The initial presentation was given Wednesday evening November 11. The theme shows the struggle of science against the ignorance and indifference with which tuberculosis has been treated in the past. Short daily dramatic broadcasts will be offered for a time to supplement the evening weekly broadcast. The *Detroit Medical News* reports that 528 physicians have registered in the campaign, which seeks to detect tuberculosis in the incipient stage. It was pointed out that during September 47 per cent of the newly found cases were in the far advanced stage. November 18 marked the opening of a series of graduate courses on the subject at the Herman Kiefer Hospital, to be held each week.

## MINNESOTA

**Personal.**—Dr. George B. Weiser, New Ulm, was guest of honor at a banquet recently, given by the Redwood-Brown County Medical Society, in recognition of his completion of forty-three years of practice in New Ulm. Dr. Weiser practiced fourteen years in Pennsylvania before coming to New Ulm. He graduated from Jefferson Medical College in 1879.

—Dr. Homer P. Basinger has been appointed health officer of Windom, succeeding Dr. Albert L. Pertl, resigned.

## MISSISSIPPI

**Supervisor of Health Education Appointed.**—Mrs. Eva Moore Adams has been appointed supervisor of health education, a newly created position in the state board of health. The health education division plans a careful survey of health needs and health problems in the state before adopting a definite program, which will be projected through the radio, newspapers and other mediums. The state department of health will soon begin the publication of a bulletin, which will be edited by Mrs. Adams.

## MISSOURI

**Director of Communicable Diseases Resigns.**—Dr. Eldred K. Musson, Jefferson City, has resigned as director of the division of communicable disease control of the Missouri State Department of Health, effective October 31. He will accept a similar position with the Kansas board of health, newspapers reported.

**Hospital News.**—Trinity Lutheran Hospital, Kansas City, observed the thirtieth anniversary of its founding during the week of October 19. The hospital admitted its first patient Oct. 29, 1906; 225 patients were hospitalized during the first year. Of the original medical staff the following are still active: Drs. Frank J. Iuen, William C. Iuen, Hal Foster, Minford A. Hanna, Carl A. Jackson and Theodore S. Blakesley.

**Society News.**—The Jackson County Medical Society was addressed November 10 by Drs. Wendell Stewart, East St. Louis, Ill., on "Pneumoconiosis with Special Reference to Silicosis," and Orville Harry Brown, Phoenix, Ariz., "What Every Physician Should Know About Clinical Allergy."—Drs. Franz J. Arzt and Garold V. Stryker, St. Louis, addressed the Marion-Ralls County Medical Society in Hannibal, October 9, on "Treatment of Subacute Pelvic Inflammation" and "Skin Signs of Hypovitaminosis" respectively.—The St. Louis Medical Society was addressed, November 10, by Drs. Julius Jensen and Carl R. Wegner on "Significance of High Blood Pressure in Pregnancy," and Jonas Curtis Lyter, "Angina Pectoris of Effort and Associated Phenomena."

**Dr. Coughlin Honored.**—Dr. William T. Coughlin, St. Louis, head of the department of surgery, St. Louis University School of Medicine, was guest of honor at a dinner given by the school, November 12, in recognition of his completion of twenty-five years' service on the faculty. Dr. Coughlin graduated from Washington University School of Medicine, St. Louis, in 1901, serving on the faculty there from 1901 to 1911, when he went to the St. Louis University School of Medicine as assistant professor of surgery. He was made head of the department in 1920. He was presented with a volume of letters of congratulation, and a collection of books is to be assembled at the university library in his honor. Other guests of honor at the dinner who have also completed twenty-five years' service on the faculty were Drs. Carl Barck, Louis C. Boislincier, Jules M. Brady, Edward P. Buddy, Cyrus E. Burford, John McH. Dean, William P. Glennon, William W. Graves, Alexander E. Horwitz, Joseph M. Keller, William E. Leighton, Bransford Lewis, Augustin P. Munsch, Louis Rasseleur, Carroll Smith, Percy H. Swahlen, Frank J. Tainter, Ralph L. Thompson and Hillel Unterberg. Rev. Alphonse M. Schwiltalla, S.J., dean of the school, presided, and Dr. Loyal Davis, head of the department of surgery, Northwestern University Medical School, Chicago, spoke on "Early Contributions of the Middle West to Surgery." The president of the university, Rev. Robert S. Johnston, also spoke.

## NEW JERSEY

**Society News.**—Dr. Oliver H. Perry Pepper, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, November 13, on "Diseases of the Esophagus from the Viewpoint of the Internist."—Dr. Warren B. Davis, Philadelphia, addressed the Hudson County Medical Society, Jersey City, November 4, on "Congenital and Acquired Deformities of the Face and Their Surgical Repair."—Dr. Arthur F. Coca, Pearl River, N. Y., addressed the Bergen County Medical Society, November 10, on "The Newer Antibodies."

## NEW YORK

**Educational Campaign on Cancer.**—The Westchester Cancer Committee conducted an educational campaign during October, concentrating on cancer of the breast. Pamphlets on this form of the disease were distributed through clubs and fraternal organizations and a special feature was a dinner attended by about 125 teachers of biology and science, superintendents of schools and physicians. A Westchester Institute of Science was organized to meet twice a year to hear cancer authorities and relay their messages to high school and college students. Clarence C. Little, Sc.D., director of the American Society for the Control of Cancer, Bar Harbor, Maine, and Dr. George T. Pack, New York, were the speakers at the dinner.

**Conference at University of Rochester.**—The University of Rochester School of Medicine and Dentistry presented a postgraduate medical conference, November 5-7, to alumni and other physicians of that section of the state. The medical faculty conducted in Strong Memorial Hospital clinical demonstrations, outpatient clinics, clinical pathologic conferences, bedside rounds and operative clinics. There was a dinner Friday evening November 6 at which Dr. Floyd S. Winslow, Rochester, president of the Medical Society of the State of New York, was toastmaster. Later the guests attended the Eastman Memorial Lecture delivered by Dr. Russell L. Haden, Cleveland, on "Clinical Manifestations of Nutritional Deficiency Diseases."

**Society News.**—Dr. Elmer B. Freeman, Baltimore, addressed the Glens Falls Academy of Medicine, October 16, on "The Practical Value of Special Diagnostic Methods in the Study of Digestive Diseases."—Dr. Edward C. Reifstein, Syracuse, addressed the Onondaga Medical Society and the Syracuse Academy of Medicine, November 17, on "The Significance of Heart Murmurs" and Dr. Tracy L. Bryant reported two cases of gas gangrene.—Dr. William D. Johnson, Batavia, addressed the Oswego County Medical Society, Oswego, November 12, on "Acute Diseases of the Abdomen."—Dr. Gershom J. Thompson, Rochester, Minn., among others, addressed the Western New York and Ontario Urological Society, which met at the Robert Packer Hospital, Sayre, Pa., October 10, on transurethral prostatectomy.

## New York City

**Hospital News.**—The family of the late Dr. Max Rosenthal recently made a gift of \$5,000 to Sydenham Hospital for a fellowship fund to finance research in medical problems. Announcement of the gift was made at the unveiling of a bronze tablet to the memory of Dr. Rosenthal, who died April 3. He was a founder of the hospital and formerly president of the medical board.—Dr. George T. Pack lectured at a clinical conference of the Memorial Hospital of Queens, November 24, on recent advances in cancer research.

**Medical-Dental Joint Meeting.**—The sixth annual Medical-Dental Convention arranged by the Joint Committee of the Organized Medical and Dental Professions of New York will be held at the Hotel Pennsylvania December 7. The morning speakers will be Dr. Samuel Feldman, on "Diseases of the Oral Cavity of Medical and Dental Interest" and Bernhard W. Weinberger, D.D.S., "Medical Problems in Orthodontia." The afternoon session will be a clinical meeting with presentation of patients. In the evening Dr. Hayes E. Martin will address the assembly on "The Responsibility of the Dental Profession in the Early Diagnosis of Intra-Oral Cancer."

**Eyeglasses for Persons on Relief.**—A clinic operated by four ophthalmologists has been placed in service by the Emergency Relief Bureau to expedite the distribution of eyeglasses to persons on relief. It is estimated that about 11,000 school children need glasses and that many adults have missed opportunities for reemployment for lack of them. Under the new plan the eye clinic will rotate among eight district relief offices covering all five boroughs. Relief recipients are given appointments at the nearest offices, thus lightening pressure on hospital clinics and reducing the delay in distribution of the glasses from five weeks to one week. The bureau is distributing about 200 pairs of glasses a week at a cost of \$2.11 a pair. It is also filling prescriptions for home relief recipients who have been examined by ophthalmologists in public and private hospitals, provided the prescriptions fall within the bureau's eligibility rules as to vision and employability.

**Society News.**—At a meeting of the New York Gastroenterological Association, November 17, the speakers were Drs. Henry A. Rafsky, on "A Study of the Glycemic Response in Patients with Biliary Tract Disease"; Reuben Ottenberg and

Ralph Colp, "Diagnosis of Surgical Jaundice," and Eilif C. Hanssen, "The Present Status of the Typhoid Carrier."—A symposium on sterilization was presented at a meeting of the section of obstetrics and gynecology of the New York Academy of Medicine, November 24, by Drs. Benjamin P. Watson, Eliot Bishop, Ira I. Kaplan, John H. Wyckoff and Foster Kennedy; Marie E. Kopp, Ph.D., and William J. McWilliams, counsel for the National Committee on Maternal Health.—Dr. Irving Schwartz addressed the New York Roentgen Society, November 16, on "Roentgenology of the Sinuses and Skull."—Drs. Boris M. Fried and Wolfgang Grcthmman addressed the New York Pathological Society, November 19, on "The 'Primary Complex'—Initial Lesion in the Childhood Type of Tuberculosis" and "Pathogenesis of Tuberculosis as a Systemic Disease" respectively.—Drs. Joseph Felsen and Albert A. Berg addressed the Medical Society of the County of Kings, November 17, on chronic bacillary dysentery.

### PENNSYLVANIA

**Society News.**—Dr. Frederick J. Bishop, Scranton, addressed the Northampton County Medical Society, Easton, November 20, on "Closer Cooperation Between Professional Men."—Dr. John B. Lownes, Philadelphia, addressed the Montgomery County Medical Society, Norristown, November 4, on problems in urology.

#### Philadelphia

**Society News.**—Dr. Nathan Chandler Foot, New York, was the guest speaker at a meeting of the Pathological Society of Philadelphia, November 12; his subject was "A Criticism of Laboratory Routine in Modern Institutions of Pathology."—Dr. Ralph M. Tyson, Dr. Henry Harris Perlman and Earl A. Schrader, M.S., among other speakers, addressed the Philadelphia Pediatric Society, November 10, on "Drugs Transmitted Through Breast Milk: Part I. A Study of Laxatives."—Dr. Linwood D. Keyser, Roanoke, Va., addressed the Philadelphia Urological Society, October 26, on "Pathogenesis of Urinary Calculi; Experimental and Clinical Survey."

**Changes at College of Pharmacy.**—Charles H. La Wall, Ph.D., for many years dean of pharmacy and formerly professor of theory and practice of pharmacy at the Philadelphia College of Pharmacy and Science, has been appointed professor of pharmacy. He retains the deanship. Ivor Griffith, Ph.M., associate professor of pharmacy, has been made assistant dean of pharmacy and professor of theory and practice of pharmacy. Arthur Osol, Ph.D., has been appointed director of chemical laboratories to succeed Prof. Frank X. Moerk, Ph.M., who became emeritus director. Adley B. Nichols, Ph.D., has been advanced to the rank of associate professor of pharmacy; John N. McDowell, Sc.D., and Linwood F. Tice, M.S., have been made assistant professors of pharmacy, and Joseph W. E. Harrison, Ph.D., has become assistant director of biologic assaying.

### RHODE ISLAND

**Society News.**—Dr. George W. Waterman, Providence, addressed the Pawtucket Medical Association, October 15, on "Pituitrin—Its Uses and Abuses."—At a meeting of the Rhode Island Medicolegal Society, October 29, Joseph H. Hagan, chief of the division of probation and parole, state department of public welfare, spoke on "Understanding the Delinquent."

**Clinic Day.**—Memorial Hospital, Pawtucket, held its annual clinic day November 4. Clinics were conducted by the staff in the morning and the following program of addresses was presented in the afternoon:

- Dr. Claude F. Dixon, Rochester, Minn., Surgical Management of Carcinoma of the Colon.
- Dr. John Eiman, Abington, Pa., Observations on Hypochloremia and Hyperchloremia.
- Dr. George M. Piersol, Philadelphia, Importance of Restoring and Maintaining Proper Chemical Balance in Chronic Renal Conditions.
- Dr. Henry L. Rockus, Philadelphia, Regional Ileitis and Ileocolitis.
- Dr. Harry B. Wilmer, Philadelphia, Glucose Tolerance and Metabolism in the Allergic Individual.
- Dr. William D. Stroud, Philadelphia, Result of Five Years' Study at Pennsylvania Hospital of Various Digitalis Preparations and the Present Attitude Toward Digitalis in the Treatment of Cardiovascular Disease.

### TENNESSEE

**Clinical Meeting in Chattanooga.**—A clinical congress was held by the Chattanooga and Hamilton County Medical Society October 15 at the Hotel Patten in Chattanooga. The guest speakers were Drs. Ray M. Balyeat, Oklahoma City; Hal M. Davison, Atlanta; Barney Brooks, Nashville, and Wilson L. Williamson, Memphis, president of the Tennessee State Medical Association.

**Society News.**—Dr. Claude C. Coleman, Richmond, Va., was the guest speaker at a meeting of the East Tennessee Medical Association in Cleveland, October 6, on "Diagnosis and Treatment of Brain Tumors." Among other speakers were Drs. Edward T. Newell, Chattanooga, on "Fractures and Dislocations of the Spinal Column"; Milton Smith Lewis, Nashville, "Treatment of Eclampsia," and Estill L. Caudill, Elizabethton, president of the society, "Acute Intestinal Obstruction."

### VERMONT

**Society News.**—Dr. Gregory Zilboorg, New York, addressed the New England Society of Psychiatry at its fall meeting in Brattleboro, October 8, on "Borderlines of Knowledge in Present-Day Psychiatry."

### WISCONSIN

**Dr. Sleyster Honored.**—The Medical Society of Milwaukee County sponsored a dinner to Dr. Rock Sleyster, Wauwatosa, Chairman of the Board of Trustees of the American Medical Association, November 14, at the Wisconsin Club, Milwaukee, in honor of his thirty-three years of service to organized medicine. Dr. Arthur J. Patek, Milwaukee, was toastmaster and the speakers were Drs. Charles Gordon Heyd, New York, President of the American Medical Association; Olin West, Chicago, Secretary and General Manager of the Association; Morris Fishbein, Chicago, Editor of THE JOURNAL; Stephen E. Gavin, Fond du Lac, president of the State Medical Society of Wisconsin; Eben J. Carey, dean, Marquette University School of Medicine, Milwaukee; Arthur W. Rogers, Oconomowoc; Chester M. Echols, president of the Medical Society of Milwaukee County; J. Gurney Taylor, Milwaukee; the Rev. Anthony F. Berens, S.J., regent of Marquette University School of Medicine, and Dr. Sleyster. In 1903 Dr. Sleyster became secretary of the Calumet County Medical Society, continuing six years. He was elected assistant secretary of the State Medical Society of Wisconsin in 1910 and secretary in 1914. He remained as secretary until 1923 and was elected president in 1924. Since 1925 he has been treasurer of the society. From 1918 to 1923 Dr. Sleyster was editor of the *Wisconsin Medical Journal*. From 1915 to 1926 he served as delegate to the American Medical Association and the last four years of that period was vice speaker of the House of Delegates. He has been a Trustee since 1926 and chairman of the Board since 1935. Dr. Sleyster was graduated from the University of Illinois College of Medicine, Chicago, 1902. He is medical director of the Milwaukee Sanitarium, Wauwatosa, a fellow of the American College of Physicians, a member of the American Psychiatric Association, the Association for Research in Nervous and Mental Diseases and the Central Neuropsychiatric Association.

### GENERAL

**Lectureship in Honor of C. Jeff Miller.**—The South-eastern Surgical Congress has established a lectureship in honor of the late Dr. C. Jeff Miller, New Orleans, who was president of the congress at the time of his death. The lecture will be given annually during the regular convention of the congress. Dr. William D. Haggard, professor of clinical surgery, Vanderbilt University School of Medicine, Nashville, will deliver the first lecture in Louisville, March 8, 1937.

**The Jacobi Fellowship.**—The Women's Medical Association of the City of New York offers the Mary Putnam Jacobi Fellowship of \$1,000 for one year for postgraduate work in the medical sciences. The fellowship is open to any woman graduate of an approved medical school. The recipient must give full time to the study of a special problem, preferably abroad; if the recipient is not a resident of the United States, the study should be made in the United States. Applications for 1937-1938 should be filed with the chairman of the committee on or before April 1, 1937. A report for publication will be required at the completion of the fellowship. The chairman of the committee is Dr. Annie S. Daniel, New York Infirmary, 321 East Fifteenth Street, New York.

**Society News.**—Dr. Charles V. Craster, Newark, N. J., was chosen president of the International Society of Medical Health Officers at its meeting in New Orleans, October 21. Drs. Eugene L. Bishop, Knoxville, Tenn., and A. G. Brito, Mexico City, were elected vice presidents and Dr. Francis E. Harrington, Minneapolis, was reelected secretary.—Dr. Joseph C. Brugman, Seattle, was elected president of the North Pacific Orthopedic Society at its annual meeting in Spokane, Wash., in September. Dr. Edward A. LeCocq, Seattle, was elected secretary.—The Pacific Northwest Society of Pathologists held its semiannual meeting in Spokane, Wash., October 10.

The subject discussed was "Lesions of the Kidney." Dr. Mathew M. Patton, Spokane, was elected president and Dr. James D. Edgar, Spokane, secretary.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

Bridgeport Hospital, Bridgeport, Conn., \$25,000 for the establishment of a free bed for indigent residents of Fairfield.

Chambersburg Hospital, Chambersburg, Pa., \$2,500 by the will of the late M. C. Kennedy.

Bronx and Beth Israel hospitals, New York, \$10,000 each, and Montefiore Hospital, New York, \$5,000 by the will of I. Miller.

New York Orthopedic Dispensary and Hospital, \$7,000 in trust bequeathed by Ella Lyon Dayan.

St. John's Riverside Hospital, \$50,000, and the Yonkers General Hospital, \$25,000, Yonkers, N. Y., by the will of Miss Mary Colgate.

Children's Hospital, Cincinnati, a residuary estate estimated at \$250,000 by the will of Mrs. Annie L. Dana.

Mount Sinai Hospital, New York, \$50,000 and New York Medical College and Flower Hospital \$10,000 from the estate of the late Charles Strauss.

Philadelphia Children's Hospital, \$10,000 by the will of the late Howard Fuguet.

New York Post-Graduate Medical School and Hospital and Babies' Hospital, New York, each one sixth of an estate estimated at about \$2,000,000 left by Miss Gertrude S. Thomas; she also bequeathed \$5,000 to the New York Eye and Ear Infirmary.

**National Society for the Prevention of Blindness.**—The annual conference of the National Society for the Prevention of Blindness will be held at the Deshler-Wallick Hotel, Columbus, Ohio, December 3-5. Sessions will be devoted to a discussion of saving eyesight in industry, eye health in relation to social work, eye health of college students, the nurses' approach to eye health, teacher education in eye health and sight-saving classes in the public schools. There will be a forum on "Rehabilitation vs. Relief," with Lewis H. Carris, New York, managing director of the society, as discussion leader. Speakers will include:

Dr. Carl E. Rice, consultant, Social Security Board, Washington, D. C.  
Dr. Ruth Boynton, University of Minnesota Medical School, Minneapolis.

C. Edith Kerby, statistician, National Society for the Prevention of Blindness, New York.

Dr. Claude S. Perry, Columbus, Ohio.

There will be a dinner meeting sponsored by the Columbus Academy of Medicine, with Dr. Edward Jackson, emeritus professor of ophthalmology, University of Colorado School of Medicine, Denver, as the speaker. His subject will be "Guarding the Sight of School Children." Audrey M. Hayden, executive secretary of the Illinois Society for the Prevention of Blindness, will address a luncheon meeting on "Selling Sight-Saving Classes to the Public." The annual meeting of the national society will be held at the Russell Sage Foundation Building, New York, December 11.

**Changes in Status of Licensure.**—The California Board of Medical Examiners recently reported the following:

Dr. Herman Gordon Bayless, Los Angeles, placed on probation for five years, during which time he shall not have or apply for a narcotic permit or have narcotics in his possession.

Dr. Leman Dow Cruise, La Mesa, restored to practice but not permitted possession of a federal narcotic tax stamp or the use of narcotics.

Dr. Milton M. Kay, Shafter, placed on probation for five years, during which time he shall not apply for or have a federal narcotic tax stamp or have narcotics in his possession.

Dr. William H. Kinsley, San Diego, license restored but not permitted to apply for a federal narcotic tax stamp or the use of narcotics.

Dr. Frederick H. C. Olberg, Redding, placed on probation for five years during which time he shall not have or apply for a federal narcotic tax stamp or have narcotics in his possession.

Dr. William B. Payton, Riverside, placed on probation for five years, during which time he shall not apply for or have a federal narcotic tax stamp or have narcotics in his possession.

The Massachusetts Board of Registration in Medicine announces the following:

Dr. Frank S. Parsons, Dorchester, license restored; it had been revoked March 10, 1927.

Dr. Percy W. Carr, River Street, Boston, license restored; it had been revoked April 26, 1934.

The New Mexico Board of Medical Examiners recently reported the following action:

Dr. John Lawrence Kirby, whose last known address was Shreveport, La., license restored October 14; it had been revoked Oct. 14, 1935, for narcotic violations.

The New York State Board of Medical Examiners reported the following action, taken September 21:

Dr. James Morris Hackett, Leonia, N. J., license revoked because of his conviction of a felony.

The State Board of Medical Education and Licensure of Pennsylvania recently reported the following action:

Dr. Richard Paul Jahnig, Reading, license restored October 23; it was suspended April 16 because of narcotic violations.

The State of West Virginia Public Health Council recently reported the following:

Dr. John B. Rosier, Salem, license revoked October 14, because of narcotic violation.

Dr. Elibugh H. Kile, Flatwoods, license restored; it had been revoked March 13, 1934, for narcotic violations.

## FOREIGN

**Personal.**—Dr. John Mellanby, Waynflete professor of physiology at the University of Oxford, and Lord Balfour of Burleigh have been appointed to the Medical Research Council in succession to Prof. Edgar D. Adrian and the Marquess of Linlithgow, who retired September 30. Lord Balfour of Burleigh has been made chairman.

**Congress on Military Medicine.**—Thirty nations were represented at the sixth session of the International Office of Documentation of Military Medicine in Geneva, Switzerland, October 12-14. Among the subjects discussed were comparative studies of medical service units in various countries; field instruction of medical units in the Swiss army; the psychologic background of the aviator; principles and means of evacuation in a combat division; panic as a war phenomenon; psychiatry in an army. The session adopted a resolution urging revision of the laws of war, which is now the subject of study by a commission created by the permanent committee of the International Congress of Military Medicine and Pharmacy (THE JOURNAL, May 23, p. 1828). The next meeting of the International Office of Documentation will be held during the ninth International Congress of Military Medicine and Pharmacy in Bucarest in June 1937.

## Government Services

### Report of Food and Drug Administration

Staple drugs showed a 91 per cent conformity to official standards of strength and purity during the past year, according to the annual report of the Food and Drug Administration. A survey carried out in the spring of this year, in which the output of 399 manufacturers was sampled, showed that in 2,246 containers analyzed, only twenty-four were below the standard of the U. S. Pharmacopeia. Unofficial drugs showed a greater violation; of 2,626 samples examined (the output of 374 manufacturers), 171 departed from the composition or potency noted on their labels.

An unusual problem in the work of the administration this year was disposition of food and drugs soaked by polluted water during the floods of last winter and spring, in which the department cooperated with federal, state and local officials. The report states that in 140 towns and cities visited by federal inspectors 1,385 carloads of water-soaked foods and drugs were kept under surveillance. Seizure under federal law was necessary in only ten instances, involving forty-one tons of stock feeds, coffee, butter, shortening, candy, cheese, breakfast foods and flour. It was estimated that about 50,000 tons of food and drugs were destroyed in the flood area.

Improvement was reported in conformity to limits established for poisonous spray residues on fruits and vegetables. The arsenic tolerance was almost universally met and most foods were found to be practically free from lead, except for accidental and preventable contamination. In 66,632 samples taken, only 146 seizures were necessary as compared with 334 in the previous fiscal year.

Canned salmon, previously showing continual improvement, was exceptionally bad, the report says. Thirteen hundred samples were taken and 294,000 shipping cases were seized. Only five seizures were made of canned tuna fish and canned mackerel was of uniformly high quality. Importations of cocoa beans, nuts, spice seeds, dates and figs were carefully supervised during the year, more than 20 million pounds being denied entry because of dirt or decomposition.

Substitution of "tea seed oil" for olive oil was detected by means of a chemical test developed by an administration chemist and 13,658 gallons of the so-called olive oil was rounded up.

A comparable fraud in the substitution of isopropyl alcohol for ethyl alcohol in "rubbing alcohol" was also run down during the year. Twenty thousand bottles were seized under a provision of the law that isopropyl alcohol preparations intended for external bodily use must show the exact nature of the article without accompanying words or trade names that would tend to confuse the product with ethyl alcohol, it was stated in the report.

During the year the administration found illegal 2,683 samples from interstate shipments of foods and drugs. Of these 2,092 were of foods and stock feeds and 591 medical and other drug preparations.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Oct. 17, 1936.

#### The Importance of Poise in a Mad Europe

In his presidential address to the Royal Medical Society of Edinburgh, Lord Horder dealt with some of the social problems of the day from the physician's standpoint and even touched on international ones. He emphasized the view that physicians could make useful contributions toward happiness and so indirectly toward health. There was a considerable overlap between these two things. He was not sure that they could do much more than had been done along the more hackneyed lines of preventive medicine, which had made good in the main. We lived longer and more healthily than we ever did. But that was not all. When he arrived at New York a few months ago, representatives of the press crowded into his cabin and asked him whether medicine had done anything recently (meaning during the past few days) to prolong life. He replied: "Surely we live long enough, isn't the problem how to live more happily?" In this the physician could help in several ways by his special knowledge and by his personal influence. There was the ministry of health and the department of health. Surely there could be a ministry and a department of public happiness. With such an ideal ministry of happiness would not the political hyperpyrexia of recent days in the east end of London (produced by a facist demonstration) and some states of political and social stress in other places be its concern rather than that of the home office (the police)? There was too much canned food for the mind.

However, whether through ministries and departments of health or by other corroborate means, the medical profession must take its share in the work. The times were critical. They were made so by the sense of imminent risk of a conflagration which a few cool heads were doing their utmost to avert. If we failed to keep our poise as a nation we might precipitate the pandemonium. Such a failure would be largely because we had too long neglected the simple factor of public happiness through the avenue of public health. For the physician there could be no left or right. For him there was expert knowledge, a rooted adherence to truth and horse sense. That British mixture was their equipment in what was perhaps the most lethal fight they had ever, as individuals and as a body, had to face, the fight for stability of mind and of body in the interest not only of national existence but of the existence of civilization. The position facing us was appalling.

He would state the desiderata in terms that were clear, however crude: 1. Enough of the right food in the belly. But it was no use telling people to drink more milk if they could not get it. At present milk costs 4 cents a gallon for making walking-stick handles and 20 cents a gallon for human food. The problem of distribution must be tackled. 2. Easy access to fresh air. 3. Shelter at a rent that left something to buy food. 4. Leisure for play, and that might lead to thinking, even high thinking. 5. Noise control.

The answer to the question why they should try to secure physical health and happiness of the people was in order that we should preserve our mental poise while large sections of humanity were losing it. This mental poise, if only we could keep it, might save civilization. But if we developed national hysteria or national hypochondriasis, this unique opportunity would be lost forever. We were told that other nations had ideals and that these stimulated them to fitness and efficiency. But we British had an ideal too that was more dearly cherished by the universal heart of mankind and therefore had more

permanence than any determined by a merely temporary objective. The deep and fundamental note in our ideal was freedom. Would that a voice oracular might peal and waken us to the realization that to maintain this ideal we must be happy.

#### The Mental Health Service

In its annual report, the board of control (the body appointed by government to control the care of mental patients) notes with satisfaction the increased proportion of patients admitted to mental hospitals without certification. The steady increase in the number of voluntary patients affords a striking refutation of the criticism, often made, that no one would enter the hospitals except by compulsion. Before the recent regulation which admits voluntary patients, admission was only on certification of insanity by two physicians. The stigma of this was so objectionable to the family of the patient that it was avoided as long as possible, with the result that the opportunity for hospital treatment in the early stage was lost.

Outpatient centers are increasing in number, but in some areas the intervals between sessions are much too long. The remedy for this is to increase the staff, not to decrease the number of sessions, for persons in the incipient stages of mental trouble are "shy creatures" and will not readily give their confidence to a physician who can see them only once a month. It is pointed out that outpatient centers cost little to maintain and are the best investment a visiting committee can make, for they will save many patients from the need of inpatient treatment.

The necessity for the appointment of trained social workers to assist the medical staff of outpatient centers and mental hospitals, and their value as links between the medical staff and the patients' homes, in relation both to treatment and to after-care, is emphasized. The diet in mental hospitals is generally good in quality and adequate in quantity, but regret is expressed that no experiment has yet been made with the cafeteria system, adopted in the United States, with a view to making the meals more attractive and improving the service. The essence of this system is that on entering the dining room the patient is given a plate which he takes to the service counter, where he is offered a choice of dishes. It might be supposed that it would lead to waste to offer patients a choice of food, but in practice it has been found that, with a little experience, the relative popularity of different dishes can be estimated. The board deplors the fact that in some mental hospitals clothing of a definitely institutional type continues to be supplied even to the better behaved women patients.

Jan. 1, 1936, the number of persons suffering from mental disorder—voluntary, temporary and certified patients—was 153,771, an increase of 1,682 over the previous year. The average annual increase for the five years that ended in 1935 was 1,714. The increased number of notified patients does not imply an increase of insanity in the general population. Of the total admissions to public mental hospitals, 24.1 were voluntary, 5.2 temporary and 70.7 certified. The increasing advantage taken of the recent introduction of voluntary admission is shown by the fact that the percentage in 1931 was only 7.1.

#### The Automatic Control of Radium

At the Westminster Hospital, where special attention has been given to radium therapy for some time, an important advance in technic has been made. The new installation incorporates a system of distant control for the better protection of operators and has allowed larger "bombs" to be used. Additional radium has been acquired to give effect to the conclusion earlier reached by the surgeons in charge of the radiotherapy department that deeper penetration can be obtained by removing the radium to a greater distance from the point of application. Four grams of radium, valued at about \$200,000, is used and is carried alternately by two bombs. By a system of auto-

matic electrical control the radium in its container can be lifted from a leaden safe into one of the bombs and swung into position over the patient. The electrical switchboard is situated 14 feet from the patient's couch. The two bombs and the radium container are made of a heavy ray-proof metallic compound recently invented. The installation, which has involved months of experimental construction and the use of expensive metals and special tools, has cost about \$4,000 apart from the radium.

#### Improved Plague Vaccine

As the result of recent discoveries at the Haffkine Institute of Bombay, a vaccine has been produced for the treatment of plague of which the protective power is increased thirtyfold. Work has been going on at the institute on the measurement of the virulence of plague cultures, and biologic methods for the standardization of plague vaccine have been evolved. This is claimed to be the first successful standardization of bacterial antigen. With a serum of the great potency thus achieved, from 70 to 80 per cent of experimentally infected animals can be saved, whereas failure has hitherto attended the use of the serums on the market. Trials in the use of the new serum in human cases are now in progress. Preliminary reports show that while the mortality in untreated cases is 76 per cent, that in treated cases has been reduced to 18 per cent.

#### Experiment with Substandard Army Recruits

An experiment with substandard army recruits is being watched with considerable interest and, if successful, its scope will probably be extended. At present thirty-two men, all of whom in one way or another did not reach the necessary standard on enlistment, have reached the twelfth day of a course that is to last three months. Yet already careful training, proper food and specialized exercises have effected a marked improvement. They are more mentally alert, they have put on weight, and their chest measurements have increased. The average increase in weight is  $2\frac{1}{2}$  pounds (1,135 Gm.). It is expected that if the present rate of progress continues the great majority of the recruits will be passed as fit for service at the end of the course. Nine of the men failed to reach the required chest measurement. One man who had been a kitchen porter had no chest expansion whatever. He has shown the greatest increase, 1 inch, while the average increase is half an inch. The normal daily ration allowance has been supplemented by extra milk and fresh fruit. Special games, physical training, remedial exercises and education figure in the course, with long walks in the country on Sundays.

#### The Smoke Evil

Presiding at the conference of the National Smoke Abatement Society, Sir George Newman, formerly chief medical officer of the ministry of health, said that he had always been impressed with the backwardness of this country in not controlling the smoke nuisance. We were very backward compared with our neighbors across the channel. Sir Leonard Hill (the physiologist) said that we had pure water and good drainage and now we must have clean air. It was far less costly to prevent than to cure disease. We lost the genial warmth and light of the sun by our dirty air. Exposure of the skin to sunlight increased the disease-resisting powers of the body, but our smoke-polluted cities interfered with this. Sir Henry Gauvain, the pioneer in this country of the open-air treatment of tuberculosis, spoke on "Light and Clean Air in Relation to Surgical Tuberculosis." He said that it was common fallacy to imagine that where sun treatment was indicated the patient should be sent to a very sunny locality where there was intense and continuous sun of high actinic value. For very strong, dark adults capable of responding to intense exposure, that was commendable. But for the majority of sick people initial weak stimulation was preferable. There were

few countries where sun treatment might be practiced under more ideal conditions in the spring and summer than in the south of England, where abundant sunshine for therapeutic purposes was available, sometimes largely in excess of the patient's need.

#### Medical School at Oxford

Lord Nuffield, automobile manufacturer, has made the munificent offer of \$6,250,000 to Oxford University for the establishment of a graduate medical school, which has been gratefully accepted. He has previously shown great interest in medical work by his benefactions to hospitals and otherwise. By discussion with the leaders of the medical profession he is well acquainted with the problems of practice and of research. He realizes that progress in medical science is reaching a stage at which it is desirable for those who work in the field of research to undergo a period of postgraduate training in modern methods of investigation, to keep in close touch with the sciences ancillary to medicine and to pursue their studies unhampered by the cares of private practice and routine teaching. Thence it is an easy step to the conception that a postgraduate medical school in a university town, in which all the scientific departments are within easy reach of the hospitals and in which the coordination of health services are established, would improve the facilities of those engaged in clinical work, whether institutional or that of general practice. In his presidential address at the recent meeting of the British Medical Association at Oxford, Sir Farquhar Buzzard spoke of the development of such a school at Oxford as an ambitious dream, thus filling the one conspicuous gap in the system of medical services. There is already at Oxford an Institute of Medical Research on a small scale, which Lord Nuffield founded. It is largely due to him that the Oxford hospitals have been reequipped and enlarged and are now provided with 650 beds. It is a condition of his offer that administration of the funds should provide for harmonious cooperation between the university and the hospitals.

The basis of Lord Nuffield's proposal is that the university, offering an environment more favorable to research than a big training hospital, should widen the scope of its medical school and of the Nuffield Institute for Medical Research for the purpose indicated. This would involve the establishment of senior posts not subject to the distractions of private practice, under whose direction there would be a body of salaried clinical assistants and house officers selected for their aptitude for research. The university would establish clinical departments of medicine, surgery, obstetrics and gynecology as well as of such other departments as may from time to time seem desirable. Each department would be under the control of a full time university professor, for whose payment the scheme provides.

#### The Physician as a Teacher

In an address to the students of Guy's Hospital, Lord Dawson said that nothing was widening the physician's horizon more than the development of preventive medicine. Physicians no longer looked after a cloistered class of sick people withdrawn from the community. Today they were more concerned with the children in the schools and the workers in the factories. More and more the physician would come to have a teaching function. Teaching how to keep well would come within his province, and the medical and teaching professions were likely to come closer and closer together. The physician could not aid those who wished to lead healthy lives unless there were suitable surroundings in which to work. It would fall to the physicians of the future to take a larger part in the life of the community and in the policy that concerned its health and vigor. Our present piecemeal social policy had no coherent purpose and was too much shaped by expediency. There was not behind it the study of scientific law and biologic facts on which alone

the health of the people could be founded. Falling death rates were matters for congratulation only so far as they denoted the preservation of people healthy enough to enjoy life and effective enough to be sound workers and sound players. Aside from this the benefits were doubtful.

### Nephrosis and Nephritis

At recent meetings of the Société médicale des hôpitaux a number of cases were reported which reflect the views of prominent internists here on nephrosis and nephritis. At the June 12 meeting, Pasteur Valléry-Radot and his associates reported a case of "lipoid nephrosis," which had been followed for four years. During the first two years, the clinical picture was that of a pure lipoid nephrosis, but even during this period of observation the presence of red blood cells in the urinary sediment had obliged the authors to alter the diagnosis so as to read "nephritis with superadded humoral syndrome of lipoid nephrosis." The subsequent evolution of the symptoms and signs confirmed this diagnosis. The lipoid nephrosis syndrome receded and the nephritis with uremic symptoms and hypertension replaced the original clinical picture of a lipoid nephrosis until the fatal termination of the case. At necropsy only the histologic changes of an ordinary chronic nephritis were to be found; hence the case was interpreted as a "nephritis with humoral syndrome of a lipoid nephrosis." The authors maintained that the case shows the lack of justification in making a distinction between a lipoid nephrosis and a nephritis. In the discussion, Cathala took exception to this opinion. He believed that a lipoid nephrosis existed as a clinical entity both in adults and in children. He cited the case of a woman, aged 28, who had an anasarca with marked albuminuria but no red cells in the urine. The blood examination was also characteristic of a lipoid nephrosis. There had been two similar transitory attacks, one at the age of 2 and the other at 18. Cathala was of the opinion that a lipoid nephrosis constitutes a special clinical entity that must be considered apart from the usual forms of nephritis. In closing the discussion, Pasteur Valléry-Radot maintained that lipoid nephrosis is rare and that it is necessary to follow a case for a prolonged period before one can say positively that no involvement of the kidney exists. If this should be done, it would soon become evident that the case was one of nephritis with a special syndrome.

A second paper on subacute nephritis due to acute lead poisoning was also read by Pasteur Valléry-Radot and his associates. The patient was a woman, aged 21, who was admitted to the hospital on account of severe abdominal pain. She gave the history of having taken 30 Gm. of a lead preparation as an abortifacient. After a primary phase, of which the principal features were vomiting, abdominal pain and stomatitis, the symptoms of a hepatonephritis appeared. The urine contained albumin and red cells. There was also a marked oliguria and high blood urea. The hepatic involvement was characterized by a subicterus and the presence of urobilin and bile salts in the urine. Sixteen months later the examination showed that a chronic nephritis was in process of development.

Cases of nephritis due to acute lead poisoning are comparatively rare. The majority of the patients die of an acute nephritis; hence one has seldom the opportunity of observing a case developing into a chronic nephritis.

### Lipoid Nephrosis Following Gold Salt Treatment

At the June 19 meeting of the Société médicale des hôpitaux the case was reported of a woman, aged 27, to whom two series of injections of gold salts had been given for a severe progressive rheumatism. The symptoms having been greatly relieved

by the first series in which 3 Gm. was given, a second series containing about the same amount was employed. About six weeks later the syndrome of a lipoid nephrosis appeared and ended fatally.

### Bone Graft to Increase Diameter of Contracted Pelvis

In the Paris letter, June 6, reference was made to a paper by Delagénère of Le Mans reporting eight cases of contracted pelvis, which were enlarged by bone grafts taken from the patients' tibias. In his paper read at the March 17 meeting of the Académie de chirurgie, Delagénère reported a case in which a normal delivery had followed sixteen months after the bone graft operation. At the July 8 meeting of the same society, Delagénère reported a second case in which he had enlarged the anteroposterior diameter of a contracted pelvis by a bone graft in June 1934 and a normal delivery had taken place in May 1936. Roentgenograms of seven of the nine cases were shown at the July 8 meeting. In three cases, dating back two years eight months, two years ten months and four years, the graft is still visible between the ends of the pubic bones.

The history of the case reported at the July 8 meeting was as follows: A primipara, aged 22, entered the clinic June 1, 1934. Several attempts to deliver the presenting head at the inlet by forceps being unsuccessful, a symphysiotomy was done, followed by delivery of a normal child weighing 5,000 Gm. Twelve days later, two grafts 6 cm. long were taken from the patient's left tibia and placed between the separated pubic bones. The patient reentered the clinic to be confined again. Radiography revealed that the separation between the pubic bones had been well maintained since the operation in June 1934. The fetus was as large as the first one, but delivery occurred spontaneously in five hours without incident.

### Close Roentgen Irradiation as Substitute for Radium Therapy

In the treatment of cancer, radium therapy has heretofore been regarded as superior to roentgen irradiation. This superiority has been particularly well demonstrated in cancers of the skin, lips, oral cavity and female genitalia. In such cases the results of roentgenotherapy were unimpressive, virtually nil. Hence centers for anticancer activities came to be established at which deposits of radium could be procured. But the supply has still been insufficient, owing to the high cost of radioactive substances. Professor Chaoul of the Sauerbruch clinic, Berlin, discussing this topic in the Berlin Medical Society, furnished the following statistics on the varying radium supply in different countries, computed for each million of population: Sweden, 1.8 Gm. of radium; Great Britain, 1.7 Gm.; Denmark, 1.8 Gm.; Czechoslovakia, 1.6 Gm.; France, 1.2 Gm.; United States, 1 Gm.; Germany, 0.3 Gm. The Swedish radiologist Forsell places the national radium supply necessary for the proper treatment of cancer at 2.5 Gm. per million of population. As the foregoing figures show, no such requisite amount has been available in any country and least of all in Germany.

In view of this situation, Chaoul undertook to experiment with so-called close roentgen irradiation and found that the hitherto assumed superiority of radium lay not in the quality of the rays but merely in the physical-technical circumstances of their application. He then attempted a carefully supervised adaptation of the circumstances of radium therapy to the administration of roentgen rays. Especially important in both therapeutic procedures was the pronounced diversity of the geometric distribution of the dosage in the tissue. In radium therapy the loss of energy in the tissue takes place quickly according to the depth and the lateral aspect. Extremely

powerful doses can therefore be delivered at the focus without any serious damage to the surrounding tissues. This is shown biologically by the preservation of the parent tissue and of the defense mechanisms necessary for the curative process. (In high voltage therapy, on the other hand, the objective is a thorough homogeneous irradiation of tissue layers and the healthy may be injured in the process.) Roentgen irradiation had therefore, like radium therapy, to be based on a decrease in dosage. It was possible to effect this adaptation by considerable shortening of the focus-skin distance, by application of proportionately soft rays and by the greatest possible restriction of the field of irradiation to the diseased area. In addition, the adaptation of both the time element and the duration of the effects of irradiation are taken into account. The biologic importance of prolonged radioactivity has in recent years been determined for radium by Régaud. In close roentgen irradiation, scattered doses were accordingly administered over a period of from three to four weeks. The assimilation of the maximal dosage too is successful; in radium therapy doses of some 8,000 roentgens are regarded as destructive of cancer and applied accordingly. In close roentgen irradiation by the restricting of the irradiated area and the scattering and extension of the dosage over several days, dosage of from 8,000 to 10,000 roentgens could be, according to Chaoul's reports, smoothly administered without any irreparable damage.

Thus, if all these requirements are satisfied, roentgen irradiation may be largely substituted for radium therapy. During the past four and one-half years 281 cancer patients were administered the roentgen treatment, the sphere of indication being the same; namely, directly accessible tumors. Chaoul outlined the successful results obtained by him: skin carcinoma cases, 93 per cent cured; cancers of the lip, 83 per cent cured; cancer in the oral cavity, 40 per cent, results in no way inferior to those obtained by radium therapy. Chaoul has also observed notable cures in cases of melanoma.

Encouraged by the foregoing satisfactory use of close roentgen irradiation in directly accessible cancer of all kinds, Chaoul is now attempting to apply the same procedure to cancer of the internal organs and thus to render surgical intervention unnecessary. Close irradiation is particularly suitable in rectal carcinoma because of the easy operative accessibility. The procedure is as follows: The coccyx and the under part of the sacrum were resected after the establishment of a preternatural anus, the rectum was drawn down posteriorly and dissected in its longitudinal aspect at the level of the tumor, and its walls were attached to the skin wound with several sutures. Irradiation succeeds then just as in superficially situated cancers; it is continued till complete atrophy of the tumor has taken place (a check should be made by repeated biopsies); then resection and so on takes place. To date this treatment has been given in only nine cases of rectal carcinoma. In seven the tumor completely disappeared, the first case has meanwhile been under observation for two and one-fourth years and the second for one and three-fourths years without any recurrence being noted. These cases are especially noteworthy if one recalls that the average expectation of life in cases of inoperable carcinoma of the rectum is one year. These results also serve to disprove the idea that carcinomas of the rectum are refractive to the rays.

Chaoul's next task will be so to improve the technic that it may be applied to those deep seated tumors for which a combined surgical and roentgen therapy is indispensable.

#### The Value of Determination of Blood Type

The National Health Council functioned as an expert advisory adjunct of the National Bureau of Health till 1933. In this capacity it instituted a subcommittee to investigate the forensic value of blood type determination and in 1929 this committee issued the following statement: "According to medicolegal

expert opinion, blood type determination when skillfully conducted is a reliable forensic aid, particularly in cases involving study of blood stains and the determination of paternity. In many such cases a decision may be arrived at by determination of the blood type when all other evidence is inadequate. Without this procedure the establishment of the facts of a case and the exculpation of a person unjustly accused of wrong-doing would in many instances be impossible." The German courts have subsequently adjudicated all cases concerning support of children and disputed legitimacy of children in accordance with this expert opinion.

But recently the minister of justice has communicated the opinion of a medicolegal expert which casts doubt on the reliability of blood type determination. This opinion sets forth that many aspects of the question call for a certain caution. As long as so much about blood typing remains obscure, a blood type finding cannot be regarded as conclusive evidence but only as indicative of probability. The minister forthwith made public a new authoritative pronouncement on the foregoing opinion by the National Bureau of Health, the contents of which are substantially as follow: The medicolegal expert is of the opinion that the determination of a blood type serves as a valuable index of probability but is inadequate as a sole means of proof in criminal procedures. This view differs from that of serologists and forensic physicians who are actually working in the field of blood typing research. Whenever he refers to so-called variant cases he has in mind that which he has long considered old and unreliable raw material. Tests of the heredity of families the members of which are completely in sympathy with the purpose of the examination and desire such examination reveal no variation (cases of illegitimacy are virtually automatically excluded from this group). In cases that present alteration of the blood group type or deviations from the generally accepted laws of heredity it has been frequently demonstrated that either the test is faulty or the children are illegitimate. Throughout innumerable legal cases the determination of blood group quality A and B and of the blood corpuscle characteristics M and N are frequently mentioned as the sole means of proof. There is no occasion, therefore, for qualification of the foregoing opinion of the National Bureau of Health. It is presumed, to be sure, that the examination will be undertaken on the basis of complete factual data.

#### Substitutes for Gold in Dental Fillings

It is reported from a convention of "dentisten" (the dental practitioners who lack regular training), held at Frankfurt-on-the-Main, that an important economic question confronts the group; namely, how the relatively large amount of gold that heretofore has been utilized in the manufacture of artificial teeth and which even today appears to be in part indispensable can be replaced by some other material. Normally, that is, in times when the gold supply did not figure so largely as it does today, the German dental physicians (zahnärzte) and the dentisten required an annual average amount of 5,000 Kg. of gold in the course of their practice of dentistry. It has been possible to decrease this required amount by some 45 per cent and the effort is now being made to effect even further reductions. In their search for a substitute material, in view of the diminishing gold supply, the dental practitioners have turned to platinum-base alloys. At the convention, discussions were submitted on silver-palladium alloys and other new metals, some of which contain gold in varied amounts. The tendency to utilize these and other white metal alloys for crowns, cast fillings and prosthetic pieces has been evident for the last two years and should partially solve the problem of a satisfactory substitut for gold. Those who advocate white metal alloy as a dental replacement material—and that means the entire group of dentisten—doggedly insist that the new metal should by no means be considered a "gold substitute" but as a new working

medium the manufacture and use of which renders gold unnecessary for many procedures of dentistry and in this way, they say, the amount of gold saved can be utilized for more urgent economic ends.

### Hemorrhagic Allergy

Prof. Giuseppe Sanarelli of Rome University, also a senator, in a lecture delivered to the physicians of the army spoke on hemorrhagic allergy, also called Sanarelli-Schwartzman's phenomenon. The speaker reviewed the difficulties in the attempts to reproduce experimentally typhoid, cholera, dysentery and intestinal anthrax. These diseases are intestinal reactions to a general infection (which is due to the entrance of specific bacteria into the blood through Waldeyer's pharyngeal lymphatic ring) rather than intestinal local infections. The phenomenon of hemorrhagic allergy was observed by the speaker, for the first time, during his studies on experimental cholera, during which he isolated accidental bacteria, especially colon bacilli, from the blood of cholera guinea-pigs. With a picture similar to that of acute cholera in human beings, death takes place in guinea-pigs which are first injected with a sublethal dose of cholera vibrio and second with a small harmless dose of a culture of colon bacilli. At necropsy epithelaxia of the intestinal mucosa (Sanarelli's phenomenon) is found in all cases. The speaker thinks that acute appendicitis is caused by a phenomenon equal to cholera epithelaxia. Owing to a condition of either chronic or subacute inflammation, the appendix acquires a condition of sensitization to the bacteria. If the latter, for some reason, enters the blood, acute appendicitis develops. The speaker succeeded in reproducing experimental acute appendicitis in rabbits by this pathogenic mechanism. He includes acute appendicitis within the chapter of hemorrhagic allergy. Schwartzman observed that Sanarelli's immunitary reaction takes place also in the skin (Schwartzman's phenomenon). More recently the reaction has been reproduced almost in all organs, with the exception of the liver, the central nervous system and the adrenals. Hemorrhagic allergy differs from anaphylaxis. Anaphylactic sensitization takes a long time to be produced and the reaction is induced by inoculation of specific bacteria, identical to the antigen that was used in sensitizing the organism. Allergic sensitization is produced in a few hours and the reaction takes place by injection of filtrates of different bacteria than the one used in producing sensitization. The speaker stated that the sudden acute crises of several diseases, such as colic pain, pneumonia and hemorrhagic pancreatitis, can be interpreted as phenomena analogous to those seen in experimental hemorrhagic allergy.

### Castellani Lectures on Italian-Ethiopian War

Prof. Aldo Castellani, head of the Clinic of Tropical Diseases at Rome University, a senator and general adviser on sanitation in eastern Africa, in a lecture recently delivered to the Istituto della Sanità Pubblica, spoke on health and sanitation of the Italian army during the Ethiopian war. There were 500,000 Italian soldiers and 100,000 Italian workers. The army mobilized 135 camp and base hospitals (with a bacteriologic laboratory and a roentgen equipment for each base hospital), fifty-five ambulatory brigades of sanitation, thirteen surgical units, fifteen ambulances for roentgen work, eleven odonto-iatric ambulances, four central laboratories, twelve brigades for disinfection, six brigades for sanitation of the soil, 139 equipments for making water potable and an abundant supply of sanitary material. The army had twenty hospitals and infirmaries along the coast and eight hospital ships, six of which had conditioned air and refrigeration centers. There were also thirty colonist hospitals. The sanitary personnel

comprised about 2,500 physicians (the majority of whom had taken courses at the Clinic of Tropical Diseases at Rome), 385 nurses of the Red Cross, 200 religious sisters and about 16,000 sanitarians and assistant workers. Diseases, especially tropical, among Italians were as follows: 1,241 cases with twenty-three fatalities from pernicious malaria, 453 hospital cases of dysentery (with a predominance of amebic dysentery) with one fatality, seventeen cases of recurrent fever with no fatalities, five cases of dengue with no fatalities and one case of smallpox, which ended in recovery. No cases of exanthematic typhus, scurvy, smallpox, leprosy, plague or cholera developed among the Italians. All soldiers were given lemon juice every other day (one lemon each). Prevention against malarial larvae could not be made. Soldiers in all ranks were daily given three tablets of quinine. In the Italian colonies of Somaliland and Eritrea, 458 cases of typhoid-paratyphoid with 161 fatalities were reported. From experience in colonial wars in the past it was expected to have a larger number, of about 50,000 Italians, taken ill and also to have a death rate of several thousand from diseases. The satisfactory services of sanitation and the hygienic and other measures taken and the administration of vaccines, especially polybacterial vaccines, resulted in the satisfactory health conditions of the troops all through the war. There were thirty cases of sunstroke, with seven deaths. The small number of cases of sunstroke, regardless of the fact that the activities took place in the torrid zone, were due to precautions taken with the troops. Drinking of alcohol was prohibited, except by the daily allowance of wine given to the soldiers at evening. All soldiers wore comfortable helmets, and transportation whenever possible was made by motor. There were many cases of dengue among civilians at Massaua when the Italian troops landed. To prevent contagion by mosquito bites the camps were placed on the highlands. Mortality of soldiers in eastern Africa was lower than that of the metropolitan army.

### Deaths

Prof. Ottorino Rossi, head of the Pavia University, director of the clinic of mental and nervous diseases in Pavia and author of several books on neuropsychiatrics, is dead.

Prof. Arcangelo Ilvento, vice director of public health, is dead. During his life he had important positions in the Italian Red Cross and the social association of public welfare. Recently he was appointed inspector of sanitation. He was a collaborator in sanitation of eastern Africa and an active worker in the prevention and crusade against malaria and trachoma. He made the basis and laws of the insurance societies against tuberculosis. He wrote several books on bacteriology, epidemiology, sanitation, social medicine, hygiene for children in schools, social aspects of tuberculosis and history of knowledge on malaria. Several of his books have been translated into other languages.

## Marriages

JAMES CLIFFORD SCOTT JR. to Miss Mary Helena Devereux, both of West Chester, Pa., September 11.

VINCENT O. LESH, South Amboy, N. J., to Dr. RUTH J. ELLIS of Fayetteville, Ark., September 4.

LLEWELLYN HALL to Mrs. Caroline Doane Fogg, both of West Hartford, Conn., September 11.

THOMAS GEORGE KNOWLTON to Miss Grace E. Kent, both of Toronto, Ont., Canada, August 22.

RICHARD STERLING HERRING, Richmond, Va., to Miss Marie Hurd of Chicago, September 2.

ARTHUR T. LEGG, Boston, to Miss Marie L. Robinson of Brookline, Mass., August 27.

JESSE POLK LOCKHART to Miss Margaret Caldwell, both of Pharr, Texas, September 10.

ALBERT G. SCHUTTE, Milwaukee, to Miss Ada Bernice Hopkins, July 18.

## Deaths

Isaac Max Rubinow, Cincinnati; University of the City of New York Medical Department, 1898; executive secretary of the social insurance committee of the American Medical Association, 1916-1917; examiner for the U. S. Civil Service Commission, 1903-1904; economic expert for the Bureau of Statistics, U. S. Department of Agriculture, 1904-1907; member of the Bureau of Statistics, U. S. Department of Commerce and Labor, 1907-1908; member of the Bureau of Labor, 1908-1911; chief statistician for the Ocean Accident and Guarantee Corporation, 1911-1916; in 1917 director of the Bureau of Social Statistics, Department of Public Charities, New York; past president of the Pennsylvania State Conference on Social Work; formerly director of the Zionist Organization of America; directed the establishment of several hospitals in Palestine, 1919-1923; for several years director of the Jewish Welfare Society of Philadelphia; had been engaged in social and editorial work; aged 61; died, September 1, in the Montefiore Hospital, New York.

Henry Farnum Stoll © Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1902; past president of the Hartford County Medical Society; governor and fellow of the American College of Physicians; served during the World War; on the staffs of Wildwood Sanatorium, Hartford, Windham Community Hospital, Willimantic, Manchester (Conn.) Memorial Hospital, New Britain (Conn.) General Hospital and the Bristol (Conn.) Hospital; aged 58; died, September 28, of coronary thrombosis.

Cyrus O. Jaster, Elyria, Ohio; Western Reserve University Medical Department, Cleveland, 1898; member of the Ohio State Medical Association; past president and for many years secretary of the Lorain County Medical Society; at various times on the staffs of the Elyria Memorial Hospital, Cleveland State Hospital and St. Alexis Hospital, Cleveland; aged 59; died, September 6, in St. Vincent Charity Hospital, Cleveland, of coronary sclerosis and pulmonary infarction.

Philip C. W. Johannes, Chicago; Northwestern University Medical School, Chicago, 1900; clinical assistant in genito-urinary surgery at his alma mater, 1904-1906; member of the Illinois State Medical Society; served during the World War; member of the staffs of the Illinois Masonic Hospital and the Evangelical Hospital of Chicago; aged 60; died, September 8, in St. Margaret's Hospital, Hammond, of injuries received in an automobile collision.

Helen Correll-Loewenstein, New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1898; for many years on the staff of the New York Orthopedic Dispensary and Hospital; aged 72; died, September 7, at her summer home in Bernardville, N. J., of arteriosclerosis, diabetes mellitus and cerebral hemorrhage.

Robert Stirton Thornton, Vancouver, B. C., Canada; University of Edinburgh Faculty of Medicine, Scotland, 1884; formerly chairman of the school board of Deloraine, Manit., and member of the legislature of Manitoba; at one time minister of education and president of the Medical Council of Canada; aged 73; died, September 18, of coronary thrombosis.

Benjamin Augustus Littell, Opelousas, La.; Tulane University of Louisiana Medical Department, New Orleans, 1888; formerly secretary of St. Landry Parish Medical Society; at various times mayor, parish coroner and health officer of Opelousas; past president of the city and the parish boards of health; aged 70; died, September 4.

Gordon Lee Hastings © Little Rock, Ark.; Medical College of Virginia, Richmond, 1926; fellow of the American College of Physicians; assistant state health officer and director of rural sanitation, state department of health; formerly health officer of Union County; aged 38; died suddenly, September 14, in Emporia, Va., of heart disease.

John Davidson Hunter, Rayne, La.; Memphis (Tenn.) Hospital Medical College, 1902; member of the Louisiana State Medical Society; formerly member of the state legislature and mayor; parish health officer; aged 60; died, September 16, in the Touro Infirmary, New Orleans, of cerebral hemorrhage.

Guy Howard Swan © Beachwood, N. J.; Michigan College of Medicine and Surgery, Detroit, 1903; member of the Radiological Society of North America; served during the World War; member of the staff of the Paul Kimball Hospital, Lake-wood; aged 55; died, September 8, of coronary occlusion.

Franklin Trumbull Wilcox © La Porte, Ind.; Rush Medical College, Chicago, 1890; formerly secretary of the county

board of health and member of the city board of health; past president of the La Porte County Tuberculosis Association; aged 70; died, September 13, of coronary occlusion.

De Witt Kluttz, Washington, N. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1918; member of the Medical Society of the State of North Carolina; for many years a member of the staff of the Tayloe Hospital; aged 47; died, September 8, of coronary thrombosis.

Charles Stanley Grahame Jr., Summitville, Ind.; Indiana University School of Medicine, Indianapolis, 1933; aged 29; died, September 23, in a hospital at Hazard, Ky., of injuries received when a motorcycle on which he was riding collided with an automobile.

John Alton Gillen © Rice Lake, Wis.; University of Minnesota Medical School, Minneapolis, 1934; on the staff of the Lakeside Methodist Hospital; aged 32; died, September 1, in St. Francis Hospital, Evanston, of cirrhosis of the liver and cerebral edema.

Clarence Light Carlton © Moline, Ill.; Northwestern University Medical School, Chicago, 1903; served during the World War; on the staffs of the Lutheran Hospital and the Moline Public Hospital; aged 65; died, September 9, of carcinoma of the colon.

Samuel Thomas Tapscott, Searcy, Ark.; University Medical College of Kansas City, Mo., 1907; member of the Arkansas Medical Society; served during the World War; aged 51; was found dead in his office, September 4, of a self-inflicted bullet wound.

Albert Smith, Parsons, Kan.; Chicago Homeopathic Medical College, 1895; member of the Kansas Medical Society; for many years a druggist; formerly on the staff of the Mercy Hospital; aged 66; died, September 13, of chronic nephritis.

James Archibald Edwards © Oakdale, Iowa; University of Nebraska College of Medicine, Omaha, 1904; superintendent of the Iowa State Sanatorium; aged 61; died, October 5, as the result of injuries received in an automobile accident.

John Herbert McConnell, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1897; fellow of the American College of Surgeons; surgeon to the Grace Hospital; aged 60; died, September 15, of coronary thrombosis.

Frederick Erastus Hyde, New York; Bellevue Hospital Medical College, New York, 1874; member of the Medical Society of the State of New York; Civil War veteran; aged 92; died, September 16, of chronic nephritis.

James Edgar Murray © Piqua, Ohio; Atlanta (Ga.) Medical College, 1893; past president of the Miami County Medical Society; on the staff of the Memorial Hospital; aged 78; died, September 5, of cerebral hemorrhage.

Hester Brewer Smith, Dallas, Texas; University of Texas School of Medicine, Galveston, 1915; served during the World War; aged 46; was found dead, September 1, of a self-inflicted bullet wound.

Archibald Adams Reid, Oneonta, N. Y.; Long Island College Hospital, Brooklyn, 1883; aged 77; died, September 13, in a hospital at Utica, of diabetes mellitus and bronchopneumonia.

Harold McClellan Allen, Toronto, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1922; L.R.C.P., London, and M.R.C.S., England, 1924; aged 40; died, August 3.

Edward Benjamin Taylor, Milwaukee; Hahnemann Medical College and Hospital, Chicago, 1897; aged 62; died, September 1, in Rochester, Wis., of coronary sclerosis and angina pectoris.

De Ruyter Howland © Stratford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1906; health officer of Stratford; aged 54; died, September 12.

William Gray Swank, Crawfordsville, Ind.; Beaumont Hospital Medical College, St. Louis, 1892; formerly city health officer; aged 76; died, September 4, of heart disease.

David Montefiore Foss, Gouverneur, N. Y.; University of Vermont College of Medicine, Burlington, 1886; aged 76; died, September 8, of myocarditis.

Martin Andrew O'Neill, Baltimore; University of Maryland School of Medicine, Baltimore, 1900; aged 61; died, September 9, of chronic nephritis.

Edward E. Whitehorne, Vesper, Wis.; Albany (N. Y.) Medical College, 1878; aged 80; died, September 16, of arteriosclerosis.

## Correspondence

### WATER, WATER, EVERYWHERE

To the Editor:—A few years ago I appealed to you as the fountainhead of information to know whether or not to give all my patients lots of physics. You did not reply but published my letter and I promptly received many replies from all over the country. Again my head is in a whirl. I find I am living in the center of the therapeutic Sahara Desert of the world. All our patients are dehydrated, desiccated and destined to destruction. They are drying up. Water, water everywhere and every one short on water. It's a sad predicament. I find it a bit difficult to determine just how nearly my patients are about to blow away, but this difficulty does not seem to be shared by many others. A hospital patient who has not had an intravenous injection of fluid the first three hours after getting well settled down between his rubber sheets has probably just neglected to engage a physician. A hospital record that does not include forced water is always laid aside for special discussion, inquiry and, probably, criticism. There is now a movement on to make it routine to hydrate all patients and then make the diagnosis, just as a friend of mine does who immediately injects solution of posterior pituitary and then determines whether or not the woman is in labor. Once in about five it saves time. As the aquatic squad approaches a ward, the patients yell "Here come the Marines."

These hydration specialists have lots of backing. You can't read anything in medicine or the lay press without being informed that you should "push water." It's about the only remedy medicine offers that all the cultists have whole-heartedly accepted; so there must be a lot to it. Every time a country newspaper adds a new medical columnist, the town waterworks has to drill extra wells. Every time the schools adopt a new and up-to-date physiology they have to add one or two fountains and some other plumbing. Some schools tried "water drinking drills" like fire drills but had to give them up because of shortage in facilities, and now we do not know and may never know whether it is safe to allow school children to face the future without these drinking drills. From my own children I learned that each child should become water conscious and react to the sight of a fountain very much as a dog does to a tree, except in reverse. They should start the day with two big glasses before breakfast and then a milk cereal. These wash out all the poisons and toxins that congregate in a child's body through the night. It seems that the child can work off the poisons that develop through the day fairly well, but the night poisons, they are something different. It takes lots of water. My younger child is a perfect convert and a great believer in school textbooks. She thought once she could hear the water chasing the poisons round about in her innerds and begged me to listen, but all I heard was bubbles. When I did not enthuse over her water program she suggested that I might be behind times, as all of her teachers had advised them many times always to drink all the water they can hold.

Every one knows that in case of a cold one should fairly swim in water. Since no one ever heard a fish sneeze, how can it be otherwise? Drinking lots of water for colds (with soda, apples or limes) always did look logical to me, for when your eyes, nose and lungs are spouting out pints of liquids it shows you are short on water or something. Besides, it seems reasonable to assume that if the water pouring out of these openings doesn't wash out the cold where it is, more water will start spoutings elsewhere and wash it out where it isn't. Plenty of water in at the top and lots of physics from the bottom will often flush out a cold before it decides where to locate, fairly catching it in midair and totally off its guard. I'll admit that I have worried a bit about the effect to gravity on a very

wet cold as compared to a dry one, and it hasn't always been clear to me how soaking up a cold till it drips will prevent it from extending itself rather aimlessly about *ad lib* and *cum laude*.

Empirically but with a fanfare of superscience, all diseases are rapidly realining themselves into two great groups, the washable and the unwashable. In the early days of this movement only a few were in the first group and it was easier to name them and regard the unnamed as belonging to the unwashable class; but we have made so much Progress that now it is far easier to name the latter and regard all others as candidates for the great flood. The definitely unwashable consist of alopecia, freckles, atheroma callus, chloasma, blackheads, dyshidrosis, dandruff and housemaid's knee. There are others but not many and you will note that they are surface diseases, just where you might think a good washing would help. Now to be fair I must add that the very wildest irrigating enthusiasts do not maintain that their universal placebo will be harmful in these cases. They merely feel that it is not definitely indicated, and after you have talked with one of them for a few minutes you will concede that that is some concession.

A friend related to me that one of the most comical sights he ever witnessed was once when he was driving through the hills of Connecticut and came to a filling station. While the regular attendant was filling his car, the attendant for the Colon Flushing Department with full equipment was chasing a half drobed and screaming woman among the outhouses and through the garden. Even after he had sold her on the idea, she still didn't know that that was where her colon was located. Such experiences practically killed the lay monopoly of this life-saving procedure and returned it to our brother disciples where it belongs, if it belongs.

Now we wash out and away the last vestige of most diseases at every natural opening of the body and if there are difficulties we punch new openings. We wash out pyelitis, even when it consists largely of cortical abscesses, and baptize nephritis regardless of conditions with the same assurance with which a colored preacher douses his converts. We add quarts of water to the diet of a patient with cystitis though it dilutes his medicine and causes extra painful voidings, to wash out what? If we know no physiology there is no thought more logical than the idea that drinking excessive amounts of water will prevent constipation. We saturate a tuberculous patient who seems disposed to dry up on our hands, for what reason? Specialists in tuberculosis claim that a dry lung is a therapeutic ideal. We force water on squishy babies whether they are dehydrated or not, and for what reason? Not that some of them do not need it but do they all, especially the squishy kind? We ask dried-up old people to increase their water intake, and who ever heard of an old person in health drinking much water? That may be one reason why they are old. We pump in large quantities, or at least we used to, in cases of threatened or actual eclampsia to wash out the "toxins" that no one can find and now learn that too much water is the cause. A patient has a traumatic head. There is not much we can do about it, so why not fill his skin and cavities with lots of water and increase his intracranial pressure? In case of doubt, give big intravenous injections. Next to blood transfusions they create the most certain impression the physician knows what to do and does it *pronto*. Never fail to take the relatives into consideration. We get a case of fits, just any kind or age, and decide instantly that everything is going out and nothing coming in, so we decide that something should go in in a big way—water—sometimes with salt, other times with sugar and other times with both and let them fight it out and let the best chemical win. Since Hippocrates we have known that during convulsions the brains are "wet" but maybe it was the wrong kind of moisture. Something has to be done. Last week a street car conductor complained that his work required that he stay with his ear and

that he did not get to drink enough for his health. I suggested a job as attendant at Boulder Dam. We prepared our prosthetics who have been damming up water in every niche of the body for months by putting them to bed, draining and forcing water for two to six weeks—that is, those do who do it that way. Maybe some have changed. Reversed hydrostatics have about ruined their renal apparatus, so these patients are asked to give nature's method, physiologic rest, reversed action and enforced maximum activity. They claim that the draining releases some of the toxins but that the washing really does the big trick. Seems as sensible as vinegar for sore eyes, but custom and usage demand the procedure. One surgeon is said to have claimed that he didn't regard his patient as adequately prepared if a spray of water did not issue from his incision.

Even I admit that there are many instances when replacing lost or strayed fluids is highly indicated, but I have about arrived at the conclusion that there are a few other instances where the procedure is "the bunk" and I have definitely decided that thirst is a fair guide for water needs for one whose mind is clear and whose gullet is open.

E. O. HARROLD, M.D., Marion, Ind.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### KETOGENIC DIET IN PETIT MAL

*To the Editor:*—I wish to ask some advice of you. I have a daughter who is 18 years old. There were no birth injuries and no other trouble except mild ileocolitis the first year. She had lobar pneumonia at 2 years, possibly with encephalitis complicating. Appendectomy was performed at 5 years. At the time of this operation her mother noticed that she turned her eyes upward and thought it just a habit. The mother told me about the eye trouble and I at once felt that she was having petit mal. This condition grew worse, until at 7 years of age she was having the spells of turning the eyes upward every two or three minutes, the attack lasting a few seconds each time. I was advised that it probably was a brain tumor. A neurologic surgeon attempted to inject air into the ventricles with no success but caused a spastic paralysis on the left side. I later put her on the ketogenic diet. That practically controlled the attacks, but she had a nutritional edema, and I discontinued the diet. I have had her seen by at least six different neurologists and neurologic surgeons, and nothing seems to be of any benefit. Also she has been through the mill of the allergist without results. At the present time these spells are harder than in the beginning, the eyes turning up and the upper part of the body nodding a little. If she is carrying a dish with something in it, she may spill something out of it but not drop the dish. At times the spells are long enough so that she may lose connection in the conversation. Early in the morning at times she may have one every three or four minutes, but as the day passes it may be half an hour between spells. When she is at her best she may not have more than one every half hour early in the morning and less frequently as the day goes on. She has had at least one general convulsion. After all these efforts it must apparently be admitted that the condition is epilepsy, possibly caused by an encephalitis at the time of the pneumonia. She did average work in school except in mathematics, in which she did poorly. She was graduated from high school last spring. In subjects like history and English she often made A and B. She is a lovable child except for being at times somewhat moody and obstinate, but on the whole she is very likable. She is beginning to see that she has a hard time maintaining her place with people and is beginning to get resentful and to seclude herself somewhat. She has an unusual amount of energy and is resentful for not being able to do more and better than any one else. She can be sent to college, but what kind, and where is there something that she can do so that she can be protected and do something of benefit to her? I should like to be advised and if you can refer me to some one capable of taking up the subject and helping me I shall appreciate it. Of course, keep in mind, in considering the case, her locality and not advise me to consider something too far away. Please omit name.

M.D., Kentucky.

**ANSWER.**—The opinion expressed regarding the nature of the attacks and the underlying cause is probably correct. There is a possibility that the attacks may yield to the administration of stramonium. The powdered leaf may be given as a test in a dose of 0.12 or 0.2 Gm. three times daily, over a period of

three or four days. If improvement is not apparent by that time, some other form of treatment should be tried. Such attacks often do not yield to phenobarbital and another trial with the ketogenic diet is worth considering. When this diet was introduced, nutritional disorders were encountered. To prevent these, yeast should be added to the diet and 1 Gm. of calcium phosphate given each night. Needless to say, the urine should be tested daily to make certain that a state of ketosis actually exists.

It is well to encourage the kind of work that leads to a normal physical, mental and social development of the patient. The patient's own wishes as to the kind of work selected should, of course, be considered, which makes it difficult to give more specific advice.

### NEPHRALGIA

*To the Editor:*—A white woman, aged 36, has a severe bilateral nephralgia extending over a period of the past six years. At the time she came under my care in June 1935, she had been getting one-half grain (0.03 Gm.) of morphine daily for three or four months. Intravenous and retrograde pyelograms show definite bilateral kinking, but no obstruction at all as evidenced by the fact that there is no dilatation at all above the kink. She is now getting the same relief from one-eighth grain (0.008 Gm.) of morphine as she formerly had from one-half grain. There is no pus or albumin in the urine, and phenolsulfonphthalein is eliminated about 80 per cent in two hours (intramuscular). General nutrition is excellent. In October she was operated on, the left kidney being freed from fat and delivered from the wound; the muscle was sutured together beneath the kidney, which was left immediately subcutaneous. Partial relief has followed on this side. Thinking that the pain might be in the nature of a neuralgia and that temporary interruption of the pain pathway might result in relief, I injected 75 mg. of procaine hydrochloride intraspinally. She had complete relief for seventy-two hours and seemed to be in Heaven, but then her pain returned as before. I am wondering whether there is any way in which the pain pathways can be interrupted, by section or injection, or if you have any other suggestions to offer. Please omit name.

M.D., Michigan.

**ANSWER.**—For a woman, aged 36, suffering with bilateral nephralgia, a limited experience apparently justifies a sympathectomy of the renal vessels and ureter on both sides. Mr. S. Harry Harris of Lewisham, Sydney, Australia, appears to be quite enthusiastic about such a procedure. It is possible that a subdiaphragmatic splanchnic nerve section with removal of the upper two lumbar ganglions may be more effective than the renal sympathectomy, since the latter operative procedure would include a sympathetic denervation of the entire urinary system rather than being limited to the kidney itself.

It would be unwise to attempt any radical procedure without the preliminary study of a nerve block. Successful splanchnic nerve blocks should be employed as therapeutic tests previous to any type of sympathectomy.

The continued use of morphine naturally arouses the suspicion of morphine addiction, for if there is an addiction the pain may not be of organic character, and therefore all operative procedures would fail.

### TOXIC ERYTHEMA

*To the Editor:*—I have a case of erythema multiforme that is very resistant to treatment and I should like you to make some suggestions as to treatment.

W. G. ELLIOTT, M.D., Cutbert, Ga.

**ANSWER.**—Erythema multiforme belongs to the group of toxic erythemas. Some authorities include many of them under the title erythema multiforme. Others insist that only those of unknown etiology presenting the typical acute lesions on the hands and feet and mucous membranes are admissible as erythema multiforme. From the statement in the query that the case is resistant to treatment, a doubt is raised at once that the case is one of the typical ones, for they usually subside spontaneously in a few weeks. There are several rare dermatoses to be considered under the heading of chronic erythema multiforme, but without a description of the case in question no intelligent surmise of its place in this group can be made. See Ormsby, *Diseases of the Skin*, Philadelphia, Lea & Febiger, 1934, pages 137 and 138. Granuloma annulare and erythema elevatum diutinum might also be considered.

If the case belongs to the group of toxic erythemas, every effort should be made to determine its etiology. The first possibility to be investigated is that some drug is responsible. Phenolphthalein, arsenphenamine, antipyrine, inorganic arsenic, mercury, potassium iodide or antistreptococcal serum may be suspected. Foods, as fish, shellfish or cheese, are sometimes responsible. The relation of erythema multiforme to purpura would accentuate this possibility. Infections, especially streptococcal infections in the teeth or the tonsils, the puerperal

uterus, malaria, gonorrhea and many other diseases not to be considered in relation to the present case are able to cause a toxic dermatitis. Syphilis rarely causes such an eruption. Bloch reported two cases of an erythema multiforme-like eruption in cases of ringworm in which trichophytin injections had been given. Tachau (*Handbuch der Haut- und Geschlechtskrankheiten* 6:616) does not admit such toxic erythemas as erythema multiforme. He limits the term to typical acute cases presenting concentrically evolving eruptions on the hands and feet, and bullous eruption of the oral mucosa, self limited but recurring from time to time. He believes that these are due to some specific cause, probably an infection yet undiscovered.

For treatment of such cases, salicylates take the first place; calcium salts are helpful. Tachau quotes W. S. Lain (*X-Rays in Erythema Multiforme*, *THE JOURNAL*, May 1, 1909, p. 1405), who used small doses of x-rays on two days in succession, and another on the fifth day of treatment, after which the lesions subsided. A recurrence thirteen days later was given similar dosage on three successive days and again subsided. The backs of the hands are quite susceptible to x-rays and six doses within three weeks would necessarily be small, probably about one-eighth skin unit (37 roentgens). This is worth trying, if investigation does not alter the diagnosis.

#### NARCOLEPSY

*To the Editor.*—Will you advise me concerning the possible causes of persistent recurring sleepiness occurring in a man of 55, a lawyer, in excellent physical condition except for a chronic sinusitis of thirty years' duration, which is probably due to an allergic sensitivity if one may judge from the large number of eosinophils in the nasal secretion and 8 per cent in the blood stream. No other organic ailments are demonstrable. The sleepiness comes on when he reaches the office in the morning or shortly after and is relieved by getting up and walking outside but again recurs. Outdoor exercise, such as golfing, relieves for several hours. He sleeps well at night and feels refreshed in the morning. This has been of some five years' duration but is gradually getting worse and interferes seriously with his work, especially when in court. I will appreciate greatly any help you can give me. If this is published, please omit name and address.

M.D., Oregon.

*ANSWER.*—The patient is most probably suffering from narcolepsy, as the attacks of somnolence appear to be truly pathologic. The inquirer does not state whether he has any attacks of weakness when he has any emotional upset, such as becoming angry, or from surprise, which occasionally occur in persons with such attacks of somnolence. He may be placed on ephedrine sulfate, 0.024 Gm. (three-eighths grain), two or three times a day, as this preparation should relieve him materially. Benzedrine sulfate has also been recommended for the treatment of narcolepsy. This preparation comes in tablets of 10 mg. each and may be given to adults in doses of two or three tablets three times a day after meals, provided there are no contraindications, such as hypertension.

#### INCIDENCE OF MULTIPLE BIRTHS

*To the Editor.*—Kindly quote the frequency of birth of twins (of the same and the opposite sex), triplets (of the same and the opposite sex) and quadruplets (are there any of the opposite sex or are they always girls?). Is there any record of five and only five fetuses? The Canadian, the Italian and the African were all six fetuses. Kindly give this your immediate attention.

M.D., Pennsylvania.

*ANSWER.*—A frequently repeated rule concerning the incidence of twins, triplets and quadruplets is Hellen's formula, according to which twins occur once in 80 single births, triplets once in 80<sup>2</sup> births or 1 in 6,400, and quadruplets once in 80<sup>3</sup> births or 1 in 512,000. Das (*J. Obst. & Gynec. Brit. Emp.* 41:227 [April] 1934) analyzed statistics concerning 186,842,231 births and found that twins occurred once in every ninety births, the highest proportion occurring in Russia and Denmark (one in seventy-one) and the lowest in Japan (one in 301). However, hospital statistics of fifteen countries showed that twins occurred once in every seventy-nine labors. Twins were more frequently born among the colored population not only in the United States but also in India.

In a series of 803 pairs of twins studied by Orel (*Arch. f. Gynäk.* 129:719, 1927) 547 were of the same sex and 256 were of the opposite sex, giving a ratio of 68.1:31.9 per cent. This author found that single ovum twins occurred in between 23 and 26.6 per cent of all cases of twins and that boys occurred with almost equal frequency in single and double ovum twins. In a study of 717,907 twins, Nichols (*Mcm. Am. Anthropol.* 4, 1907) found that both children were males in 234,497, both were females in 219,312 and they were of opposite sex in 264,098.

Triplets may be of single, double or triple ova and they may all be of the same sex or there may be two of one sex and one of the opposite sex.

According to Hellen, quadruplets occur once in 512,000 births, but according to Gruelich (*Am. Naturalist* 64:142, 1930), who analyzed 120,061,398 pregnancies, quadruplets occurred once in 727,159 deliveries. Quadruplets may be monozygotic, dizygotic, trizygotic or quadrazygotic. They may be all male, all female or of both sexes. Pryor (*Am. J. Anatomy* 59:409 [Sept. 15] 1936) was able to find only five sets of quadruplets in the United States that have reached the age of 2 years or more.

About thirty cases of quintuplets have been reported. The incidence of this occurrence has been estimated as one in 41,600,000 pregnancies. Dr. Dafoe, who attended the Dionne quintuplets, reported the case in *THE JOURNAL*, Sept. 1, 1934, p. 673, and he made no mention of a sixth fetus. According to De Lee there is only one authentic case of sextuplets.

#### LEUKOPLAKIA BUCCALIS

*To the Editor.*—A man, aged 27, single, noticed six months ago some white smooth milky patches at the tip on the dorsal surface of the tongue, to which he had not given any importance. Three days ago he noticed that these white areas have spread to the middle third of the tongue. Irregular white smooth areas alternating with coarsely infiltrated areas were found on the upper surface of the tongue from the middle third to the tip. On the margins of the organ, cracks and deep rhagades could be plainly seen; on squeezing, no exudation was elicited. On instrumental manipulation, pain is not felt. The blood Wassermann test is negative; the patient has not enough money to pay further diagnostic expenses such as for a spinal fluid Wassermann test. Taste sensitiveness is normal. Tobacco (smoking and chewing) and the liquor habit are not indulged in. There is no evidence of a chancre that may suggest syphilis. I am inclined to diagnosis this case as leukoplakia buccalis despite the emphatic assurance of the patient that he does not use tobacco or liquor. Your opinion with regard to diagnosis and suggestion as to treatment will be deeply appreciated. Please omit name.

M.D., California.

*ANSWER.*—This case is most probably one of leukoplakia buccalis associated with a scrotal tongue. While a certain number of these cases are associated with syphilis and heavy smoking, it is possible for these to be absent in some cases. Poor hygiene of the mouth, carious teeth, and ingestion of highly seasoned, spiced and hot foods may be contributory factors and should be ruled out. Other conditions that must be considered are lichen planus, which may be limited to the buccal mucosa, but, as a rule, the characteristic angular, violaceous, itching papules are usually present on the flexor aspects of the wrist and about the ankles, with associated lesions on the body. The buccal and tongue lesions usually appear as smooth or fissured plaques, with a tendency to occur in rings having linear striae and covered by a silver white pellicle.

Monilial infection of the tongue must also be considered. In this condition there are usually white, scroll-like patterns, and the area is covered by a shiny, gelatinous, translucent membrane. Microscopically, monilial or other yeastlike organisms are found.

Leukoplakia buccalis is best treated by care to the hygiene of the mouth and teeth, the use of antiseptic mouth washes, and the destruction of any thickened or ulcerated areas by electrocoagulation, radium or carbon dioxide snow.

Lichen planus calls for systemic treatment with mercurials or arsenic by mouth or, preferably, by injection.

Monilial infections are best treated by a saturated solution of gentian violet and the use of a sodium perborate mouth wash.

#### STERILIZING DIAPERS

*To the Editor.*—Will you please give me a formula for a chlorine solution for sterilizing diapers? Please give directions for use. Kindly omit name.

M.D., Michigan.

*ANSWER.*—A chlorine solution for sterilizing diapers is not generally recommended. The chlorine salts are rather strong chemicals, and not only might they be injurious to the fabric of the diaper but they might also irritate the baby's skin if the chlorine solution has not all been removed from the cloth. It has been the practice in bleaching cloth when calcium hypochlorite is used to neutralize with sodium bisulfite after the bleaching process, in order to avoid injury to the material of the cloth.

The simplest and most efficacious method of sterilizing diapers is to wash them well in soap suds, rinse out the suds in clear water and then boil the diapers. After the diapers are dried, preferably in the sun, they may be pressed with a hot iron. In cases of "ammoniacal diapers" it has been recommended that in addition to the routine laundering the diapers

be soaked in a solution of boric acid (two heaping tablespoonfuls of boric acid powder to a quart of water). The diapers are not rinsed after soaking in the boric acid solution but wrung out and dried. Traces of boric acid left in the diaper neutralize ammonia and also retard the growth of bacteria that produce the ammonia.

#### ATROPHIC ARTHRITIS

*To the Editor:*—A man, aged 40, had the usual childhood diseases. In 1920 he had a tonsillectomy but a moderate sized tag was left in. In 1921 he was given 1,500 units of tetanus antitoxin for a trivial puncture wound. There was no reaction from the serum. Four years ago he contracted a mild pharyngeal diphtheria for which he was given 10,000 units of diphtheria antitoxin intramuscularly. One week after this he developed a severe serum reaction. There was an intense urticaria lasting for three days. The itching was so intense that it necessitated almost constant bathing with alkalis. Epinephrine gave transient relief. There was swelling of the lips and eyelids and apparently some edema of the glottis, as evidenced by hoarseness and slight difficulty in breathing. Joint symptoms were severe. The urticaria and edema gradually disappeared, but the pain and stiffness in the joints persisted. This was especially noted in the knees when walking was first attempted. The joint symptoms have spread so that there has been involvement of all the joints. There is moderate crepitation on motion in the wrists and in one ankle. The patient has a chronic arthritis of the atrophic type. At the time of the serum reaction the patient had two devitalized but not abscessed teeth; they had been roentgenographed a short time before. He also had the small tag of tonsil previously mentioned. He is of the asthenic type, 71½ inches (182 cm.) in height and weighing about 140 pounds (63 Kg.) at the time of the serum reaction. He was otherwise in good physical condition. At the present time the arthritis seems to be progressing and the joint symptoms are more severe. Foci of infection have been removed but no other therapy has been instituted save for analgesics for pain. Is chronic arthritis a very uncommon occurrence following severe serum sickness? What is the relationship between the serum reaction and the chronic arthritis? Would the patient have been likely to develop an arthritis if he had not had this severe serum reaction? Would you treat this condition any differently than any other case of chronic atrophic arthritis? Please omit name. M.D., North Dakota.

*ANSWER.*—Serum disease is a definite clinical entity and as represented in this case the injection of tetanus antitoxin provoked the formation of antibodies in the tissues. The second injection of antigen in the diphtheria antitoxin reacted with the preformed antibody resulting in anaphylactic shock.

The inquirer does not mention the presence in the patient of other symptoms of atrophic arthritis beyond pain and stiffness of the joints nor does he indicate the time interval between the anaphylactic reaction and the onset of active joint disturbance, such as swelling or discoloration. Joint pains have been known to persist for quite some time following serum sickness, although serum disease per se is not generally regarded as a cause of atrophic arthritis. What probably happened in this case is that the patient was already "marked" for arthritis and the serum reaction served merely as a precipitating cause. In almost all cases of atrophic arthritis it is possible to discover a precipitating cause, which involves some unusual drain on the patient's resistance and serves to transfer the patient from the prearthritic state into the arthritic state. Among the more common precipitating causes are respiratory infections, surgical operations, childbirth, severe nervous shock and gastro-intestinal upsets.

The treatment of this patient should include the usual measures of recognized benefit in atrophic arthritis. Since calcium is believed to be beneficial in anaphylactic conditions, it might be advisable to give this drug a trial.

#### DYSCHONDROPLASIA

*To the Editor:*—Would you please give me whatever information you may have available regarding dyschondroplasia or multiple congenital enchondrosis? I know of such a case in a man, aged 24, involving the left forearm and left lower leg. There is a shortening of the left ulna, and bony exostoses in the left ulna, left scapula and left tibia. The condition has been present since birth. Incidentally, the father and sister of this man suffer from the same condition. Could you give me any opinion as to the prognosis and any possible type of treatment? If this query is published, please omit name. M.D., Wisconsin.

*ANSWER.*—Dyschondroplasia, with or without exostoses, was so well described by Ollier in 1898 that it has been called by his name. There is no known etiologic factor but its hereditary tendencies have long been recognized. The growth changes are attributed to defects in the primary germ cell and have no relation to any postnatal complications. Only bones that are preformed in cartilage are affected.

Exostoses that cause disturbances of locomotion or function should be removed and deformities may be corrected by osteotomy, but there is no specific treatment that is known at the present time.

#### EXCESSIVE HIRSUTY IN WOMEN

*To the Editor:*—A woman, aged 24, single, complains of growth of hair on the face and the chest, male distribution on the abdomen, moderate growth on the arms and thighs, present since childhood. The menses set in at the age of 13, occur every twenty-eight days, and last four or five days. The pulse is 84, the blood pressure 110 systolic and 70 diastolic, the height 5 feet 3 inches (160 cm.), the weight 108 pounds (49 Kg.), the hemoglobin 65 per cent. The thyroid is slightly enlarged; the extremities are warm. The breasts are well developed and firm. On the ground that the anterior pituitary extract is supposed to produce hair growth in certain alopecias, is it logical to assume that the anterior pituitary body is hyperfunctioning in this case and that the use of an antagonistic gland will produce a disappearance of the excessive growth of hair? What gland is antagonistic to the anterior pituitary? The patient has had occasional right frontal headache during the morning hours, worse in damp weather, for five years. Tonsillectomy was performed five years ago for frequent sore throat. General bodily weakness and a postnasal drip have existed since an attack of sinusitis four years ago. Could an adrenal gland tumor be the causative agent? Is thyroid indicated? No pelvic examination was attempted, since the organs are presumed normal on the basis of normal menses and breast development. Please omit name. M.D., New Jersey.

*ANSWER.*—Excessive hirsuties in the female may be due to a variety of causes, any one of which or a combination of all may be operative. These may be summed up as follows:

1. An overactive pituitary, particularly the anterior lobe.
2. An adrenal disturbance involving the cortex, usually of the tumor type.
3. A deficiency of ovarian hormones, or certain types of ovarian tumor.
4. An overactive thyroid.

The possible causes will have to be analyzed to determine the basis for the condition.

The question as to which gland is antagonistic to the pituitary is difficult to answer, for the anterior pituitary contains apparently a large number of special hormonal agents, each one of which would have its own antagonist. The whole situation is one that is exceedingly complicated and it actually involves an investigation into the entire endocrine balance.

The unilateral frontal headaches would suggest a pituitary disturbance; the rapid pulse, with an enlarged thyroid, would suggest hyperthyroidism.

A pelvic examination ought to be made if possible to determine the presence or not of an ovarian tumor; an examination of the adrenals should be made for the same purpose. A roentgenogram of the head showing the pituitary fossa and a basal metabolic test should be made.

Nothing has been said about lineae atrophicae, either purple, pink or white, which occasionally appear on the thighs, abdomen or shoulders in these cases; if these are present it would indicate an anterior lobe deficiency allied to the Cushing syndrome.

#### QUARTZ FRAGMENT IN LENS CAPSULE

*To the Editor:*—For the past six months a miner has been carrying a piece of quartz, a 1 mm. cube, on the anterior lens capsule of the eye. The symptoms are unilateral diplopia, central "shadow" effect, and prism "rainbow" in bright light. On examination the eye presents no evidence of irritation. There is a small leukoma at the limbus where the foreign body entered and the quartz is clearly visible in the midpupillary zone on the anterior lens capsule, dropping slightly on changing the position of the head but fixed to the lens capsule. As I am unable to find authority in the literature available to me, I should like the following information: 1. If left alone, what is the prognosis? 2. If properly removed now, could one expect an opaque scar in the anterior lens capsule or possibly precipitate a traumatic cataract formation? 3. Is it safer to wait until signs of irritation develop (if any) and only then remove the foreign body? 4. If the quartz should drop off the lens capsule into the anterior chamber in the future, might it scarify the endothelium or even Descemet's membrane sufficiently to impair vision? 5. Kindly cite authority on subject. GEORGE S. WEISS, M.D., Winnemucca, Nev.

*ANSWER.*—1. If the condition is left alone, it is probable that a complete traumatic cataract will ultimately develop. The reason is that the piece of quartz must be embedded in the anterior lens capsule; otherwise it could not remain in the described position. Consequently there must be a solution of continuity of the capsule. With such a condition there will be a gradual seepage of aqueous into the lens through the capsule rupture and eventual cataract formation (Weiss, O.: Physiology of Nutrition of Eye, Kurzes Handbuch der Ophthalmologie, vol. 11). A few cases have been reported of foreign bodies entering the lens through a minute tear in the capsule, which closed immediately afterward without formation of cataract (Elschnig and others, 1910).

2. Both.

3. It is not probable that there will be any signs of irritation in that eye. As long as the quartz remains in situ and does

not come in contact with the uvea, no inflammation is to be expected. Consequently, removal of the foreign body may be postponed indefinitely.

4. Probably not.

5. There seems to be no record of intra-ocular quartz foreign bodies in the literature and only an occasional reference to foreign bodies that have remained adherent to the anterior lens capsule without penetration. The statements that are made regarding intra-ocular pieces of glass undoubtedly hold true for intra-ocular quartz. For references, see Wagenmann: *Injuries* (Graefe-Saemisch Handbuch der gesamten Augenheilkunde, edition 2, pp. 1395 and 1399) and Cramer, E.: *Injuries* (Kurzes Handbuch der Ophthalmologie, volume IV).

#### MR. ALBERT PAYSON TERHUNE AND THE PHYSIOLOGY OF FEAR

*To the Editor:*—Will you please inform me whether the following statement by Albert Payson Terhune, which appeared in the *Reader's Digest*, is true: "Do not allow fear to master you when you are in the presence of an ill-tempered or vigilant dog. My reason for stressing this may sound fantastic, yet it is an established scientific fact. When you are frightened, nature pumps an undue amount of adrenalin through your system. This throws off an odor said to be like that of formic acid, which human nostrils fail to detect. Dogs, however, hate it. It rouses some of them to contempt. Many an otherwise inoffensive dog will attack when that odor reaches him." A. J. REICH, M.D., New York.

*ANSWER:*—Mr. Terhune's advice not to let fear master you is sound, whether you face a dog or any other potential danger, but the reasons given for expression of fear as a factor of safety are, if not fantastic, at least not based on known or proved facts. Intense fear may, indeed, cause some increased secretion of epinephrine. Even this is in dispute. But there is no evidence that increased epinephrine leads to exhalations from the body, exhalations inducing "hate" and "contempt" in the canine species. We know, for a fact, that many hundred times the normal output of epinephrine may be injected intravenously in dogs, and man, in the presence of dogs, with the latter showing no "hate" or "contempt" detectable by man. If and when an otherwise innocuous dog attacks a man in a state of fear, it is probably due to the man's action rather than to his odors. To be sure, a person in great fear may lose control of his sphincters, but the ordinary human nose is not immune to the odors thus released; these odors are not like formic acid, and science knows of no evidence that they induce hate and contempt in pups.

#### ACIDIFICATION OF URINE

*To the Editor:*—Recently I have been having difficulty with my patients following transurethral prostatectomy. In spite of the fact that there is no residual urine, the urine remains persistently alkaline, and there is a large amount of triple phosphate and calcium phosphate crystals in the urine. Patients also complain of a great deal of terminal burning and some frequency. The patients experiencing this trouble are mostly from a district where the water is very hard and contains alkali. I have used acid sodium phosphate, ammonium nitrate and ammonium chloride in an attempt to acidify the urine, without success. I would appreciate any suggestion that you could offer for relief of this condition. Kindly omit the name. M.D., South Dakota.

*ANSWER:*—In all cases in which acidification of the urine is aimed at, an acid-forming diet should be resorted to even prior to or jointly with medication. Such diet includes all animal foods, excepting milk, and all cereals, while fruits and vegetables must be excluded. In resistant cases the ketogenic diet should be resorted to, giving, for example, water flavored with tea and saccharin for two days and adding to this 350 cc. of whipped cream on each of the following three days.

#### PILONIDAL CYST

*To the Editor:*—A man, aged 28, has had a pilonidal cyst since 1931. He has had two radical operations, but the sinus has recurred each time and the patient has not improved following the operations. He has consulted some of the best men in the country, who have suggested that the sinus may connect with the spinal canal through the sacral foramina and account for the persistence of the sinus. If it does connect with the spinal canal, what mode of treatment would you suggest? If there is any literature on this subject, kindly give me references. Please omit name. M.D., South Dakota.

*ANSWER:*—Probably a portion of the cyst still remains. In order to make sure of its extent, the sinus may be injected with thorium dioxide sol 20 per cent. After the injection roentgenograms should be made in both the anteroposterior and lateral positions. This will in all probability outline the exact extent and locality of the cyst.

Only occasionally does the cyst extend into the spinal canal. When this occurs, the cyst must be removed in order to effect a perfect cure. It probably does not come within the subarachnoid spaces.

#### EFFECTS OF LONG CONTINUED USE OF BARBITURATES

*To the Editor:*—Mrs. B. G. J., aged 58, has for several years had hypertensive cardiovascular renal disease. When I first saw her about one year ago I prescribed pentobarbital sodium capsules 1½ grains (0.1 Gm.) three times a day for relief of pain. Since that time she has continued to take them, consuming on the average six capsules a day. Aside from the mere habit formation, will you please outline for me the deleterious effects from such a rate of consumption of this drug. Also, what would you suggest that I prescribe to take the place of it? Please omit name. M.D., Texas.

*ANSWER:*—A search of the literature fails to reveal reports of deleterious effects from such habitual consumption of pentobarbital sodium, though this may be ascribed to the rather recent introduction of the drug than to lack of possibility of their occurrence. Acetylsalicylic acid is an excellent analgesic, acting in a different manner from that of pentobarbital sodium and with well known untoward effects that may be watched for. The gradual substitution of this for the other drug by combining the two in the same capsule may solve the problem.

#### HEMIATROPHY OF BODY

*To the Editor:*—I have a patient on whom no laboratory work has been done and I am at a loss as to where to begin. A girl, aged 4½ years, apparently normal in all other respects, has for the past year had an arrested development on the same side, from the shoulder girdle to the hand and from the gluteal region to the foot. The hand and foot are much smaller than those of the opposite side and the muscles of the fleshier parts much wasted. Can you help diagnose this case? Please omit name and address. M.D., Iowa.

*ANSWER:*—The patient is affected by a condition known as hemiatrophy of the body. At best it is difficult to determine the etiology of this disorder. As a rule it is congenital in origin, though one should not fail to make careful neurologic examination. In some instances hemiatrophies may be traced to a birth injury with a resulting infantile palsy, though in the absence of paralysis, spasticity, other neurologic changes and a carefully obtained history, focal cerebral lesions may be excluded.

#### DEPRESSIVE PSYCHOSES OF MANIC-DEPRESSIVE TYPE

*To the Editor:*—Is there any evidence that you know of to show the sexual etiology of the depressive psychoses of the manic-depressive type? Are there any statistics to show that these depressions occur in eunuchs or in women who may have had their ovaries removed in early life? Any data or references you may be able to offer on this particular topic will be greatly appreciated. Kindly omit my name. M.D., New York.

*ANSWER:*—Depressive psychoses of the manic-depressive type are prone to develop in persons who are constitutionally predisposed to them, under conditions of stress of various kinds. They occur not uncommonly at puberty and the climacteric, particularly the latter, whether it occurs spontaneously or is induced artificially. There is no evidence that eunuchs are particularly prone to them. This, however, does not establish a sexual etiology. The stresses of exhaustion, bodily illness, pregnancy and lactation may also precipitate attacks of depression, and the same is true of emotional stress in reaction to situations in the outside world.

#### PNEUMONIA FOLLOWING INJECTION OF SERUM

*To the Editor:*—A man in excellent health punctured his foot on a nail at 8 o'clock in the morning. Two hours after this he received an injection of antitetanic serum and developed, the next day, lobar pneumonia followed by pleural effusion. Is there any connection between the injection of serum he received and the lung reaction he developed? Please omit name. M.D., Canada.

*ANSWER:*—No.

#### "OPHTHALMOSCOPIC SIGNS OF DEATH"

*To the Editor:*—I should like to comment on your reply to Dr. Wyatt Barnes's inquiry about the ophthalmoscopic signs of death (*THE JOURNAL*, October 24, p. 1408) in which you state that "the interrupted blood column makes its appearance only in the veins." I have seen the blood column interrupted in the arteries at the time of death, and my own experience is corroborated by C. H. Usher (*Ophth. Rev.* 15: 339, 1896). As a matter of fact, the article quoted as your reference (*American Encyclopedia of Ophthalmology* 5: 3784) reads "These interruptions . . . are apparent chiefly in the veins."

GORDON M. BRUCE, M.D., New York.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, Jan. 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Reciprocity*. Los Angeles, Dec. 16. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, Jan. 5. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Post, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: *Medical*. Des Moines, Dec. 1-3. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines. *Basic Science*. Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

KANSAS: Topeka, Dec. 8-9. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY: Louisville, Dec. 2-4. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

LOUISIANA: New Orleans, December. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MARYLAND: *Regular*. Baltimore, Dec. 8. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 5-6. Sec., Dr. J. C. ... .. Jan. 19-21. Sec., Dr. Julian F. Du Bois, 35 ... ..

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Endorsement*. Raleigh, Nov. 30. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 434 S. 3rd St., Grand Forks.

OHIO: Columbus, Dec. 2-4. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, Dec. 9. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 9-13. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 19. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada in December. *Practical or clinical examination* will be given in St. Louis in April. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Des Moines.

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. *All applications for this examination must be filed before Dec. 1, and case reports must be submitted before Jan. 1*. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. *Only applications received by the Secretary on Dec. 1 or before will be acted upon by the Board*. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D.C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester.

AMERICAN BOARD OF UROLOGY: Chicago, Dec. 4-6. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

### Texas June Report

Dr. T. J. Crowe, secretary, Texas State Board of Medical Examiners, reports the written examination held in Austin, June 23-25, 1936. One hundred and eighty-two candidates were examined, 163 of whom passed and 19 failed. One hundred applicants were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Northwestern University Medical School.....	(1936)*		1
Tulane Univ. of Louisiana School of Medicine (1935),	(1936)		2
Johns Hopkins University School of Medicine.....	(1928)		1
Harvard University Medical School.....	(1936)		1
Creighton University School of Medicine.....	(1933)		1
University of Nebraska College of Medicine.....	(1936)		1
Columbia Univ. College of Physicians and Surgeons.....	(1936)		1
University of Pennsylvania School of Medicine.....	(1936)		1

## Book Notices

**The Thyroid: Surgery—Syndromes—Treatment.** By E. P. Sloan, M.D.  
Edited by Members of the Sloan Clinic, Guy A. Sloan, M.D., et al. And  
with a foreword by Wm. Seaman Bahndridge, M.D. Cloth. Price, \$10.  
Pp. 475, with 99 illustrations. Springfield, Illinois, & Baltimore: Charles  
C. Thomas, 1936.

This work of E. P. Sloan is edited posthumously by the members of his clinic and is divided into twenty chapters. While much of what is stated in discussions on anatomy, physiology and endocrinology are known facts, the question of the etiology of endemic goiter is thoroughly considered. The work of Crotti, of a contagium vivum as the exciting cause of endemic goiter, gives much food for thought. It is pointed out that Crotti's conception is upheld by McCarrison. Iodine insufficiency, mineral imbalance and catalytic agents as possible etiologic factors are scrutinized. The author's hypothesis disagrees with the usually accepted pathogenesis of dysthyroidism. He also offers a classification of the divers types of goiter by dividing its pathology into four main groups, adding a number of subdivisions to each. A survey of preventive measures and the pathology of thyroid disease, as well as symptomatology, diagnosis and prognosis, are ably discussed. The therapeutic aspects of thyroid disease (nonsurgical and surgical) are well handled. In the former the author believes that mineral deficiency as related to thyroid disease is of the "utmost importance" and he recommends the use of sodium phosphate in 20 to 30 grain (1.3 to 2 Gm.) doses three times a day, as advocated by Kocher many years ago. This may be augmented by the use of phosphorus, calcium and sulfur, the last suggested in the form of sulfonated bitumen (ichthammol), with which he has had "unusual success in both toxic and atoxic goiter." On the successes reported by the roentgenologist in the treatment of toxic goiter by means of x-rays, Sloan fails to find "incontrovertible conclusions concerning the efficacy" of such treatment. Twenty per cent of his series of cases were subjected to roentgen treatment previous to coming under his observation; fifty per cent of these patients stated that they were "improved" and, while classed as cured, they have not been "entirely well." The other fifty per cent reported no results from the treatment. An analytic study of the pros and cons of radium treatment is interesting. Commenting on the use of x-rays in intrathoracic goiter, the author says "In this type of goiter harm is done more often than anything else." He recommends its use, however, in malignant disease of the thyroid. Chapter 10 deals with the surgical treatment of thyroid disease. It is an excellent chapter. A comparative study of anesthetics is added. Commenting on basal anesthetics, the author states that the combination of morphine and scopolamine when used in proper dosages produces ideal anesthesia. He adds that "barbital cannot be used with safety for complete anesthesia but for the control of mental states previous to operation." The illustrations and colored plates by William B. McNett are well executed.

While the technical steps of thyroidectomy are standardized perhaps, the author justly remarks that every goiter surgeon has a tendency to develop his technic along certain lines and to introduce little innovations and improvements, but that the author finds that "this [his] fully developed technic is in his hands immeasurably better than any other." The reasons for the various technical steps are carefully discussed and, rather ingeniously, Sloan compares his method of thyroidectomy with obstetric delivery. He speaks of "flexion," "rotation" and "delivery" as pertaining to removal of the thyroid. For completeness of the cycle, the author may as well have compared dividing the prethyroid structures as "rupture of the membranes" and exposure by retraction as "dilation." The complications arising during thyroidectomy and their treatment are

succinctly described. The chapter on postoperative management contains many valuable hints on the avoidance of complications and how to steer the patient through postoperative thyrotoxic crises. The chapter on the parathyroid and thymus glands are no less thorough than are the others. The final two chapters on the history, nomenclature and classification afford much information and interesting reading. The former traces interest in diseases of the thyroid to the pre-Christian era, thence down to the present, and from pioneers to contemporary thyroid surgeons. As especially prominent in thyroid work in America are mentioned Halsted, Rogers, Ochsner, Mayo and Crotti. In speaking of the last named, he calls attention to the fact that Crotti in 1917 published "the first comprehensive treatise on diseases of the thyroid." The effect of this book upon the development of the modern conception and treatment of thyroid disease is hard to evaluate. In this classical treatise he brought together all the worthwhile thought and all the investigations which had been done up to that time and by making this knowledge accessible the appreciation of the importance of the goiter problem was enhanced." A thorough bibliography completes the work. All in all the book is interesting, is well written and contains a vast amount of information.

**Studies on the Aetiology and Pathogenesis of Cataracta zonularis.** By Gunnar von Bahr, Med. Lic., G.B.G. An Academic Treatise Which by Due Permission of the Most Experienced Faculty of Medicine at Uppsala Will be Publicly Defended in the Lecture Room of the Physiological Institution Saturday, May 23rd, 1936, 10 A. M., to Obtain the Degree of Doctor of Medicine. Paper. Pp. 240, with illustrations. Uppsala: Almqvist & Wiksells Boktryckeri-A.-B., 1936.

This is an academic treatise which "by due permission of the most experienced Faculty of Medicine at Uppsala will be publicly defended in the lecture room on May 23, 1936, to obtain the degree of Doctor of Medicine." The author reviews all that is known about cataracta zonularis or capsulolenticularis arida siliquata or perinuclearis from the first description in 1800 to date. This occupies exactly half of the book. The remainder is devoted to the technic and results of rat feeding experiments in the production of congenital zonular cataract. The work is good, and definite conclusions can be drawn that the lenticular opacities result in animals in which experimental rickets is complicated with tetany. The condition apparently causes an injury to the superficial lens fibers with the resultant slow development of the cataract, even though the tetany may disappear. This conclusion is not entirely new, as much of this work has been done previously by others; but von Bahr's work corroborates much of the earlier work and allows of a clear exposition. The bibliography, comprising fourteen pages, is complete. The last four pages are actual photographs of the experimental animals and do not show much. There is nothing revolutionary or excitingly new in all this, but the book does represent careful conscientious work and is praiseworthy. Would that there were more pieces of work of this type emanating from the younger men in this country.

**The Comparative Anatomy of the Nervous System of Vertebrates, Including Man.** By C. U. Ariens Kappers, M.D., Sc.D., LL.D., Director of the Central Institute of Brain Research, Amsterdam, G. Carl Huber, M.D., Sc.D., and Elizabeth Caroline Crosby, Ph.D., Associate Professor of Anatomy in the University of Michigan. Volumes I and II. Cloth. Price, \$16, per set. Pp. 864; 865-1845, with 710 illustrations. New York: Macmillan Company, 1936.

An appraisal of this great work requires first some reference to its authors and its historical setting. Ariens Kappers, a pupil of Edinger and during the past twenty-five years director of the Central Institute of Brain Research at Amsterdam, has devoted his whole life to investigation of the comparative anatomy of the nervous system. This program was broadly conceived, was followed with industry and acumen, and has now reached its natural consummation in a comparative investigation of the human brain from the standpoint of its evolution and racial characteristics. In 1920 and 1921 he published in two massive volumes his *Die vergleichende Anatomie des Nervensystems* (Haarlem, de Erven F. Bohn), which has remained the only comprehensive reference book in this field.

Ten years ago, when Dr. Ariens Kappers wished to reissue this work in English, in his search for a collaborator he naturally turned to Dr. Crosby, whose thorough familiarity with the field and fidelity to high ideals of accuracy and fitness gave

promise of preeminent qualifications for the task. In this he was not disappointed, for she did the work of translation and rewriting to bring the material down to date so acceptably as to win respect and admiration. Here one can speak without qualification, for in a letter to the reviewer Ariëns Kappers writes "The part Dr. Crosby had in this work is by far the greatest. I hope this will be realized wherever this book is used." It is a pleasure to record in this connection that her own university has recently promoted Dr. Crosby to full professorial rank.

During the progress of this work the late Dr. Huber joined the staff and his ripe scholarship, editorial experience and exacting standards of scientific and literary excellence contributed much to the success of this remarkable achievement. The proficiency of the publishers should not pass without comment, for, despite an unexpected combination of difficulties, they have produced an unusually good example of book making.

The product of this collaboration is a serviceable summary of the best research in the field covered, a summary which is greatly needed, for much of this literature is in relatively inaccessible publications and all of it is technical and hard for the human neurologist to assimilate. It is strictly comparative. The human brain is adequately treated from this standpoint; that is, each region is considered in its comparative and phylogenetic relationships. There is no systematic description of it as a whole, for this is available in other manuals. For the same reason there is little reference to the extensive literature on brain weights and measurements, racial differences and other neurologic aspects of physical anthropology, to which Ariëns Kappers himself has recently contributed so extensively. Summaries of these topics are given in his shorter work, *The Evolution of the Nervous System in Invertebrates, Vertebrates and Man* (Haarlem, 1929).

The first chapter, on the evolution and morphology of nervous elements, is more heavily weighted with theory than any other part of the work. The other chapters, however, are not mere compilations of descriptive details, for the authors everywhere look for general relationships and do not hesitate to advance their own theoretical interpretations. Chapter II is devoted to the spinal cord from *Amphioxus* to man (pp. 135-334); chapter III to taste and the general afferent systems of the medulla oblongata (pp. 335-432); chapter IV to the lateral line and acoustic systems (pp. 433-515); chapter V to the efferent systems of the medulla oblongata and midbrain, with illustrations and discussion of Ariëns Kappers' principle of neurobiotaxis (pp. 516-644); chapter VI to the coordinating apparatus of medulla oblongata and midbrain (pp. 645-695), and chapter VII to the cerebellum (pp. 696-864). These seven chapters comprise volume I.

In volume II, chapter VIII embraces the mesencephalon and diencephalon (pp. 865-1239); chapter IX the telencephalon, except neopallium (pp. 1240-1516), and chapter X the development of the cortex in mammals (pp. 1517-1713). The last chapter is of especial interest to students and practitioners of human neurology, for here at the culmination of the evolutionary series are fully illustrated discussions of the evolution of fissural patterns, cortical lamination, and patterns of anatomic and physiologic localization.

The work is well documented, and extraordinary care has been taken to ensure the accuracy of these references. The bibliographies appended to the chapters comprise a total of 272 pages, and these judiciously selected titles include most of the significant literature. The index of 131 pages lists every reference to each author and topic treated. The printing is clean and few misprints have been noted, though there are some lapses, as on page 1660, where the citation of figures 636, 640 and 641 refers to the German text of 1921 and should read figures 709 and 710 of the present text. On page 852 the entry C. J. Herrick, 1895, should be C. L. Herrick, and on page 1280 *Lepidosteus* is referred to as a dipnoan. Figure 423 (fig. 408 of the German text) is based on a crude diagram of the median section of the brain of *Amblystoma* published by Herrick in 1910. It is unfortunate that the errors of this sketch are perpetuated in the revision, for more accurate figures are now available. In the chapter on the cerebellum the fundamental work of Larsell is not adequately recognized, perhaps because his papers on its morphology and development in lower mammals appeared after this text was completed. Larsell's

researches have clarified the morphology of the cerebellum on the basis of more detailed and critical comparative analysis than has heretofore been made.

The blemishes noted are of minor importance in comparison with the general excellence and accuracy of the whole. This is really a new work, not merely a translation and revision of the old. It is indispensable to every serious student of the vertebrate nervous system, for there is no comparable manual in any language, and it will doubtless remain the standard book of reference in this field for many years to come.

*Voprosy entsefalografii v detskom vozraste. S prilozheniem atlasa, risunkov i entsefalogramm. Pod redaktsiei S. A. Reynberga. [Problems of Encephalography in Childhood, with Atlas, Drawings and Encephalogram.]* Cloth. Price, 6 rubles. Pp. 107, with 137 illustrations. Leningrad: Ogliz-Blomeditz, Leningradskoe otdelenie, 1936.

The problems of encephalography are presented in the form of essays emanating from the Leningrad Clara Zetkin Scientific-Experimental Institute of Mother and Child Welfare. Since 1929, 170 children have been subjected to the encephalographic method of study at the institute. In fifteen cases the roentgenologic data were controlled by necropsy. There is a chapter by M. A. Toporkova on the technic of the method and a description of an original head bandage in the form of a loop. In a chapter by D. S. Lindenbraten the reader will find a detailed anatomic study of roentgenologic presentation of the brain and its coverings. The approach to the interpretation of encephalograms in pathologic conditions is based on the study of the normal as gleaned from numerous observations of normal brains of children. Two papers by Lindenbraten and H. H. Keler present a combined roentgenologic and clinical study in the various disorders of the brain and the meninges. They present clinical-roentgenologic syndromes of postmeningitic and post-encephalitic processes, birth trauma, tumors, microcephaly, cerebral hemiplegia, hydrocephalus and a few of the rarer diseases. The authors made encephalographic studies in seventy-three cases of epilepsy. They emphasize the lack of parallelism between the clinical signs and roentgenograms. An atlas of drawings and encephalograms is appended. This collection of essays because of considerable material and careful study should prove of interest to the pediatrician and the roentgenologist.

*Vascular Disorders of the Limbs Described for Practitioners and Students.* By Sir Thomas Lewis, C.B.E., F.R.S., M.D., Physician in Charge of Department of Clinical Research, University College Hospital, London. Cloth. Price, \$2. Pp. 111, with 5 illustrations. New York: Macmillan Company, 1936.

This excellent volume is written by an internationally known authority who has written eight volumes previously, dealing chiefly with circulation. Most of the material is from papers by the author and his associates, previously published in *Heart* and in the first two volumes of *Clinical Science*. The absence of controversial data and of a bibliography greatly lessens the value of the book, which is clearly a presentation of the author's explanations and opinions. He admits frankly in the preface that the book is not a comprehensive account of vascular disorders of the limbs. Since several arterial diseases and diseases of the veins and lymphatics are not considered, the title of the volume is somewhat misleading. The author states in the preface that "the time is opportune to attempt to outline conceptions of certain peripheral disorders of the circulation in a way that may prove useful to those engaged, not in research, but in practice." There is grave doubt that the volume will serve this purpose, since diagnosis and treatment are presented incompletely and inadequately. Almost the entire presentation is that of a clinical physiologist interested in mechanisms rather than in diseases.

The chapters on the circulation in the limb and its testing and on the effects of circulatory arrest are excellent. In the chapter on embolism and thrombosis of the main arteries the origin of emboli in the extremities from arteries, particularly the aorta, is overlooked and the explanation of the marked diminution in circulation following arterial embolism is not convincing. Certainly the effects of embolism on circulation are more profound than those of simple ligation or compression of an artery, and this needs further consideration. In the section on the treatment of arterial embolism, methods of increasing collateral circulation are incompletely presented. The short chapter on "postischemic contracture; intermittent claudication"

appears complete, but the thirteen pages on "arteriosclerosis; thrombo-angiitis obliterans" are deficient in many regards. The chapters on "vasoconstriction; local arterial spasm" and on "spasmodic arterial obstruction; Raynaud's phenomenon" are clearly and concisely written. However, the explanation of the uniformly good results that follow sympathectomy for Raynaud's disease of the lower extremities in contrast to occasional failure of good results to follow sympathectomy for Raynaud's disease of the upper extremities is not convincing. Recent investigative work on this problem is not mentioned. The author believes that Raynaud's disease is a manifestation of local fault in digital arteries and that it is not attributable to overactivity of the sympathetic nervous system. His extremely fair attitude toward sympathectomy for Raynaud's disease is conspicuous, for he writes: "Belief or disbelief in the theory that the malady is due to overaction of the sympathetic should not be allowed to weigh for or against operation. The justification of the treatment is to be founded upon experience and not upon theory." The chapter on "gangrene (bilateral forms; cervical rib; general)" is excellent, but the one on "vasodilatation; flushing" leaves much to be desired. It is quite clear that much remains to be done in this field. The term "erythrocyanosis" is used in place of the commonly used terms "cutis marmorata" or "livedo reticularis" but does not appear to be a better designation. The reader may question the accuracy of the statement that "it came in with short skirts and thin stockings and will go out with them." Objection is given to the term "erythromelalgia," and "erythralgia" is suggested as more appropriate. Since the term "erythralgia" is not even included in a standard medical dictionary and since "erythromelalgia" is an accepted medical term, it seems advisable to retain it. Trial of sympathectomy is recommended for this malady, but no reason is given for this recommendation and no results are mentioned. Sympathectomy appears illogical, since pain in this condition is aggravated by increasing the temperature of the skin, an inevitable result of sympathectomy. The final chapter, on vascular disorders in diseases of the nervous system, is clearly written and contains much valuable information.

This book is a superb volume of explanations of mechanisms of circulatory disturbances, although it is of little value to the physician whose chief interests in peripheral vascular diseases are diagnosis and treatment. It is heartily recommended to every student of vascular diseases, since within its covers are to be found explanations of many of the puzzling phenomena observed in abnormalities of peripheral arterial circulation. It is the sort of book which can be read more than once with pleasure and referred to on numerous occasions with profit.

**Security Against Sickness: A Study of Health Insurance.** By I. S. Falk. Cloth. Price, \$4. Pp. 423. Garden City, New York: Doubleday, Doran & Company, Inc., 1936.

This study is predicated on the assumption that some plan for prepayment of sickness costs is necessary to enable certain groups of the population to obtain medical care. The author, who was the associate director of study on the administrative staff of the Committee on the Costs of Medical Care, claims that it was unfortunate during the depression years that "no program of sufficient scope was developed in this period to deal adequately with the major problems or even to hold the promise of effective action on a large or national scale." The author states that the studies represented in part in this volume, undertaken in 1933, were to seek out the principles on which constructive action should rest particularly with respect to certain problems that arise out of illness and its social and economic sequelae. Much of the statistical material is drawn from or is a restatement of the statistics contained in the reports of the Committee on the Costs of Medical Care. Material published by individuals and organizations committed to the adoption of some form of state managed medicine is used freely. Part two of the study is devoted to a review of the compulsory sickness insurance systems in Germany, France and Denmark and the compulsory health insurance in Great Britain. The reader gathers the impression from the discussion of these foreign systems that the author is disclosing these facts for the first time. The discussion of the statistics of the German system omits comments on the reduction in the amount of demanded medical service with the fall of the value of the mark and omits other interpretations of the German statistics

which would have made the discussion more fair and valuable. The author presents the basis of an American program in part three. In the nineteen fundamental principles which the author has formulated as the essentials for an American system, he has endeavored to amalgamate into one program the tenets of the proponents of state managed medicine and some of the objections of those who oppose such a system. Nowhere in these principles is it recognized that food, clothing and housing are sometimes of greater importance to the individual than medical care. This study gives a definite impression that it is an effort to revive or to extend the pronouncements contained in the Majority Report of the Committee on the Costs of Medical Care. The twelve appendixes contain reports, statements of principles and official actions of various groups on the subjects of medical and hospital service. It appears that these quotations are included only for reference. The study itself contains in 361 pages a renewed effort to establish in the United States a system of state managed medicine.

**Etude de l'influence des glandes endocrines sur le squelette.** Par le Docteur G. Coryn. Vol. XI, Fasc. 1-2, Archives internationales de médecine expérimentale. Publiées par R. Bruynoghe, professeur d'hygiène et de bactériologie à l'Université de Louvain, et A. P. Dustin, professeur d'anatomie pathologique à l'Université de Bruxelles. Paper. Pp. 403, with 94 illustrations. Liège: Imprimerie H. Vaillant-Carmanne, S. A., 1936.

This is in reality a monograph which adequately reviews the pertinent literature referable to the influence of the endocrine glands on the skeleton. The author takes up in order the hypophysis, the sex glands, the parathyroid gland, the thyroid and the adrenals. He has included in each chapter critical analyses of the subjects reviewed and has included case reports that illustrate the conditions under discussion. This is one of the most comprehensive reviews which has appeared in a voluminous literature on this and related subjects during the past decade. For all who are interested, both because of the content of the text and because of the excellence of the bibliography, the book is recommended.

**Preventive Medicine.** By Mark F. Boyd, M.D., M.S., C.P.H., Member of Regular Field Staff, International Health Division of the Rockefeller Foundation. Fifth edition. Cloth. Price, \$4.50. Pp. 561, with 155 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

New editions of this book have succeeded each other at fairly regular intervals of three to five years since the original publication in 1920. The last previous edition was in 1932, since which time, according to the preface, many sections, including those on colds, ringworm, psittacosis, diphtheria, encephalitis, poliomyelitis, pneumonia, tuberculosis, malaria, typhus and relapsing fever have been either wholly revised or newly written. Recent developments in sewage treatment are noted, and sections dealing with mottled enamel and the rat from a public health standpoint have been added. More extensive consideration is given to the vitamins, silicosis and recent data relating to general morbidity. This edition retains the characteristics of previous editions in being easily readable and carrying a high degree of accuracy. It illustrates, however, in the section on the epidemiology of the amebic dysentery outbreak of 1933 in Chicago, the difficulty inherent in keeping any textbook thoroughly up to the minute. This section already needs revision. The continued demand for the book and the sustained quality of its contents are sufficient evidence of its practicality especially as an introduction to the subject of preventive medicine.

**Birth Control Laws: Shall We Keep Them, Change Them or Abolish Them.** By Mary Ware Dennett. Cloth. Price, \$2.50. Pp. 309. New York: Frederick H. Hitchcock, 1936.

This book is obviously propaganda for the removal of federal and state restrictions on the importation, manufacture and distribution of devices and materials wherewith to prevent conception and for the removal of restrictions on the dissemination of information concerning the prevention of conception. It was copyrighted in 1926 and bears no evidence of having been changed since that date. Those who are interested in the ten-year old views of the lay authoress concerning the development of restrictive legislation in the field of contraception, and concerning the status and future of such legislation ten years ago, may find the book interesting.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Cancer of Breast Allegedly Due to Trauma.**—The plaintiff, a tenant in an apartment building, sued the executrix of the owner of the building for personal injuries sustained as a result of an explosion of a hot water system. From a judgment of \$30,000 in favor of the plaintiff, the defendant appealed to the Supreme Court of Missouri, division 1, and contended, among other things, that the damages awarded were excessive.

The evidence showed that the plaintiff received fractures of her right arm, both ankles, and her skull; that she sustained severe first, second and third degree burns on her arms, neck, shoulders and back, which left residual scars; that she had impairment of function of her right hand and wrist as a result of the fracture of that arm, and that she would always suffer from headaches and dizzy spells as the result of her skull fracture. In addition to these injuries, a cancer developed in her left breast which her medical testimony tended to show was the result of trauma and due to injuries received in the explosion. She underwent three operations for the removal of the cancerous growths and finally had to have her entire breast and part of her pleura removed. The medical testimony further showed that more cancerous growths had developed which could not be removed because they were too near her lung and that they would ultimately cause her death. It was further shown that at the time of the explosion she was 29 years of age and was in good health. The Supreme Court, while it did not decide whether or not the cancer was due to trauma, held that it was proper for the jury to consider this testimony in fixing the amount of damages. The court concluded that the damages were not excessive.—*Vitale v. Duerbeck (Mo.)*, 92 S. W. (2d) 691.

**Conjunctivitis from Soot as an Occupational Disease.**—The plaintiff, during the course of his employment, was required to cut holes in chimneys as an incident to the installation of gas burning appliances. As he was cleaning the debris from the chimneys, soot would get on his hands, arms, and shirt sleeves. Habitually he would wipe perspiration from his face with his hands and sleeves. After working about a month, his eyes began to smart and, suspecting the soot as the causal factor, he notified his boss, who apparently minimized the probability that the soot had anything to do with the smarting of the eyes. The eye condition grew progressively worse, acute conjunctivitis developed in his left eye, and, in spite of medical treatment, the upper eyelid turned inward so that the eyelashes scraped the eyeball, necessitating an operation for the removal of part of the lid. After the operation, his eyes continued to trouble him more or less, especially on cold days, when there would be excess lacrimation and blurring of vision in both eyes. The plaintiff brought a common law action for damages against the company, and the Kansas City court of appeals, in a divided opinion, affirmed the judgment of the trial court for the plaintiff. (79 S. W. [2d] 1063.) On the request of the dissenting judge, however, the case was certified to the Supreme Court of Missouri, division 2.

The Missouri workmen's compensation act, at the time this cause of action arose, excluded from its operation occupational disease in any form. The principal issue in this case was whether the employee's injury resulted from an occupational disease or from an accident within the meaning of the workmen's compensation act. If the injury resulted from such an accident, then the present common law action was not maintainable, the workmen's compensation commission having original jurisdiction of the case. The question of what constitutes an occupational disease, said the Supreme Court, was discussed at length in *Wolf v. Mallinckrodt Chemical Works*, 336 Mo. 746, 81 S. W. (2d) 323 (abstracted in THE JOURNAL, Dec. 7, 1935, p. 1940), in which it was held that combined sclerosis, under the facts in the case, was not an occupational disease because the plaintiff had failed to show that it was peculiar or incident to employment. In the present case there was expert testimony which tended to prove that soot from coal

smoke contained an amount of caustic substances sufficient to irritate a person's eye and that repeated injections of soot into the employee's eyes in the manner testified to by him could have produced the injurious consequences of which he complained. Both in the *Wolf* case and in this case the evidence showed that the condition complained of could have resulted from other causes, not connected with the occupation in question. Likewise, in both cases there was no evidence that any person had ever suffered a similar trouble growing out of a similar occupation. In the present case there was no evidence to show that the employee's trouble was "peculiar and incident to the work or process" or that it was "a disease contracted in the usual and ordinary course of events, which, from the common experience of humanity, is known to be incidental to a particular employment."

The employee's evidence not only failed to show that the injury or disease was peculiar and incident to the work carried on or that it was contracted in the usual and ordinary course of events incidental to his employment, but it showed that it was in the nature of an accident. The employee did not get the soot in his eyes as a usual concomitant or result of the work he was doing, as where one breathes dust laden atmosphere in his working place. He got it on his hands in the ordinary course of his work, but it was communicated to his eyes by his own thoughtless act in wiping sweat from his face with his soot covered hand. He knew each time that occurred, because each time he felt the smarting sensation in his eyes. Had it occurred but once, or a few times within a short period, and resulted in injury, there could be no doubt that it would properly be denominated as an "accident" within the meaning of the workmen's compensation act. The producing cause of the injury in this case did not occur, however, at one time or within a few days, but, by what may be denominated a series of similar accidental occurrences, over a period of four or five weeks. The employee first felt the smarting in his eyes when he had been at work three or four weeks. When he had been working about two months his eyes became sore. This was an unexpected and unforeseen event. The event happened suddenly because, even though the infection was gradual through a period of four or five weeks, instead of a single accidental injury, there was a series of accidental injuries culminating in the same consequential result. The Supreme Court concluded, therefore, that the employee had sustained an accidental injury within the meaning of the workmen's compensation act and that therefore a court of law lacked jurisdiction over the case. The judgment for the employee was consequently reversed.—*Downey v. Kansas City Gas Company (Mo.)*, 92 S. W. (2d) 580.

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Cleveland, Jan. 11-13. Dr. Philip Lewin, 104 South Michigan Blvd., Chicago, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otolological Society, Boston, Jan. 7. Dr. D. C. Jarvis, Quarry Bank Bldg., Barre, Vt., Chairman.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Alfred Lewy, 25 East Washington St., Chicago, Chairman.
- Mid-Western Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Frederick A. Figi, 436 Tenth Ave., S.W., Rochester, Minn., Chairman.
- National Society for the Prevention of Blindness, Columbus, Ohio, Dec. 3-5. Mr. Lewis H. Carris, 50 West 50th St., New York, Managing Director.
- Puerto Rico, Medical Association of, San Juan, Dec. 18-20. Dr. Dolores M. Pinero, Ave. Fernandez Juncos, Parada, 19, Santurce, Secretary.
- Radiological Society of North America, Cincinnati, Nov. 30-Dec. 4. Dr. Donald S. Childs, 607 Medical Arts Building, Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, New York, Dec. 5. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Society of American Bacteriologists, Indianapolis, Dec. 28-30. Dr. I. L. Baldwin, College of Agriculture, University of Wisconsin, Madison, Wis., Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Memphis, Tenn., Jan. 13. Dr. Charles D. Blassingame, Physicians and Surgeons Bldg., Memphis, Tenn., Chairman.
- Southern Surgical Association, Edgewater Park, Miss., Dec. 15-17. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Texas Ophthalmological and Oto-Laryngological Society, Fort Worth, Dec. 4-5. Dr. Kelly Cox, 1719 Pacific Ave., Dallas, Secretary.
- Western Surgical Association, Kansas City, Mo., Dec. 11-12. Dr. A. H. Montgomery, 122 S. Michigan Blvd., Chicago, Secretary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

Amyloidosis of Lungs and Heart. H. W. Ferris, New York.—p. 701.

**Structural Changes in Lungs in Mitral Stenosis.**—To ascertain the significance of pulmonary and vascular lesions in mitral stenosis, Parker and Weiss studied nine cases of mitral stenosis of rheumatic origin. The lesions in the pulmonary vessels consisted of intimal thickening of the arteries and hyperplastic arteriolar sclerosis and arteriolar necrosis. The changes in the alveolar walls were marked dilatation of the capillaries, increase in the thickness of the capillary basement membrane, increase in the interstitial tissue (collagen), interstitial pericapillary edema and a tendency of the flat epithelial cells to become cuboidal in shape. The normal thickness of from 1 to 3 microns of alveolar tissue through which oxygen and carbon dioxide have to diffuse can increase up to a thickness of from 30 to 50 microns. Even in the presence of an advanced degree of thickening of the alveolar wall and of the capillary basement membrane, the alveolar basement membrane remains normal. With progressive pulmonary engorgement, first the visible capillaries increase in number, and only later do they dilate. Often the capillaries become displaced and are separated from the alveolar surface by a considerable degree of edema or by thick layers of collagen. Pericapillary and intra-alveolar edema frequently develop independently. Permanent structural alterations in the lungs caused by circulatory failure interfere with the gaseous exchange. In the causation of the pulmonary arterial and arteriolar lesions, an important part is played by the prolonged combined presence of high intravascular pressure, stagnation of blood flow and edema. The similarity between the clinicopathologic syndrome of pulmonary hypertension with malignant sclerosis and advanced cases of mitral stenosis is pointed out.

**Meningococcal Myocarditis.**—Saphir emphasizes the occurrence and the clinical and pathologic significance of meningococcal myocarditis and reports two fatal cases. Both patients (two of ten) showed meningococcal meningitis. In the first case the culture of the cerebrospinal fluid remained negative. The short stay (two days) of the patient in the hospital prevented obtaining another specimen. Smears from the cerebrospinal fluid, however, showed the characteristic gram-negative intracellular biscuit shaped diplococci. Because of this

and the presence of the intracellular gram-negative diplococci in the inflammatory lesions of the myocardium, it seems clear that the cause of the myocarditis was a meningococcal bacteremia, even though absolute proof is missing. In the second case a pure culture of meningococcus was obtained from the cerebrospinal fluid, in addition to finding the organism in the smears from the cerebrospinal fluid and in the sections of the cardiac muscle. Histologically the myocarditis is characterized by hemorrhagic exudate, the early appearance of large endothelial leukocytes, the early destruction of muscle fibers and the presence of intracellular gram-negative diplococci. The foci of necrosis are similar to those seen in the myocardium in instances of subacute bacterial endocarditis. Although in both hearts the lesions were more or less diffuse, the bundle of His was involved, showing polymorphonuclear leukocytic infiltrations and hemorrhage. In view of the prevailing opinion that the primary lesion in meningococcal meningitis is a meningococcal bacteremia (Herrick), it is not surprising that occasionally meningococci may be the cause of an isolated myocarditis. It is likely that the associated myocarditis with resulting myocardial failure seriously influences the prognosis, not only because of the impending myocardial failure but also because it seems that the myocarditis is the result of an overwhelming infection with meningococci. The abrupt death of the first patient may be explained by the overwhelming infection with meningococci, resulting in myocarditis.

### American Journal of Psychiatry, New York

93: 249-502 (Sept.) 1936

Control of Behavior, Its Mechanism and Evolution. C. J. Herrick.—p. 249.  
Neuroses and Neuropsychoses: Relationship of Symptom Groups. A. Myerson, Boston.—p. 263.

John Addington Symonds: Case: Study in Esthetic Homosexuality. L. J. Bragman, Binghamton, N. Y.—p. 375.

**Psychoses Lying Between Schizophrenia and Manic-Depressive Psychoses.**—Hunt and Appel observed thirty patients with an even mixture of schizophrenic and manic-depressive features. Of these, eleven recovered and remained well, six recovered and had one recurrence followed by recovery, three recovered but had two or more recurrences and ten were unrecovered, never having a remission, for the most part going on to definite schizophrenia. The recovery rate is therefore roughly twice as good as it is said to be in schizophrenia and from 25 to 50 per cent poorer than that found in pure manic-depressive psychosis. The factors common to the group as a whole were early age of onset, neuropathic heredity, mixed cycloid and schizoid personality traits, a rather high incidence of somatic factors in the illness, a serious precipitating factor in more than half, and a high incidence of persecutory trend, somatic preoccupation and hallucinations.

**Leukoplakia Buccalis.**—After studying 316 cases of leukoplakia, McCarthy is convinced that in a high percentage of cases extensive involvement of the tongue is definitely related to syphilis but that there is no evidence to indicate a relation between the greater number of instances of leukoplakia observed elsewhere in the oral cavity and syphilitic infection. The predisposing factor in leukoplakia of the tongue is atrophic glossitis of syphilitic origin, occurring in untreated or inadequately treated patients with syphilis of long standing. This type of glossitis, with the secondary sheen of hyperkeratotic leukoplakia, presents a picture almost pathognomonic of syphilis. A characteristic picture of leukoplakia of the tongue is smooth red atrophic areas interspersed with more or less generalized leukoplakic lesions. Frequently the tongue is involved in a sclerotic process with secondary lobulation. The same surface leukokeratotic process is usually associated with this type of glossitis. In contrast to the picture presented by syphilitic glossitis is that of the reaction of the normal tongue in heavy smokers, in whom the hypertrophy and leukoplakia are confined to the papillae, producing a thick, roughened, whitish surface. Constitutional factors have been suggested as important in predisposing a person to leukoplakia or in actually causing it. A lack of vitamin A may result in atrophy of the lingual papillae and predispose the patient to lingual leukoplakia. A hereditary predisposition to degeneration or atrophy of tissue, allied to so-called cancer susceptibility, may be a factor. Leukoplakia is overwhelmingly prevalent in men. This disparity between the sexes may change in the course of time, since women have taken up the use of tobacco. The course of the disease depends entirely on the cause and on preventive and local treatment. Except for the preventive form of treatment, the removal of the irritating factor in the mouth and abstinence from the use of tobacco, the treatment of leukoplakia is unsatisfactory. When the use of tobacco is an etiologic factor and the patient continues to use it, the removal of the leukoplakic lesion is usually followed by a recurrence. The author confines treatment to the use of electrodesiccation and electrocoagulation by monopolar and bipolar high frequency current. The use of radium in the treatment of leukoplakia of the tongue associated with atrophic syphilitic glossitis is provocative of a malignant growth when the treatment is given in small doses over a long time. The use of locally applied irritating or caustic remedies is contraindicated, as there is a possibility of stimulating malignant change in the lesion. The surgical removal of the malignant lesion is indicated in some cases, but in cases of leukoplakia involving the tongue this procedure is often carried to a more radical degree than necessary and the electric current is preferable.

**Xeroderma Pigmentosum.**—Macklin declares that, contrary to statements made in textbooks of dermatology, xeroderma pigmentosum is found to be inherited, the determiners for which are passed on in the germ plasma from parent to child. It is transmitted as a recessive condition. Consanguineous marriages are found far more frequently among parents of patients with xeroderma pigmentosum than among the general population, the minimal incidence being 21.2 per cent in the series collected. The two sexes are affected equally. Because of the average small size of families, there are more families with one child affected than those with more than one. This does not preclude the possibility or even probability that in any family a second child may be affected. The disease affects males and females equally and may affect both sexes in one family.

**Gastroscopy.**—The extrinsic contraindications to gastroscopy that Symonds lists are aortic aneurysm, enlarged thymus or other tumor and diseases of the spine interfering with mobility, and the intrinsic ones are advanced organic disease, extensive varicosities and acute esophagitis (corrosive and necrotic). Gastroscopy is indicated in every case of persistent or unexplained symptoms referable to the stomach. The indications of special interest are acute and chronic gastritis (chronic, without or associated with additional pathologic processes), gastric symptoms with negative roentgenograms, gastric neurosis, unexplained gastro-intestinal hemorrhage, peptic ulcer, differential diagnosis between ulcer and cancer, and neoplasms. Many cases with gastric symptoms with negative roentgen observations and so-called gastric neurosis may be proved by gastroscopy to be gastritis. In the performance of gastroscopy the patient should be in a relaxed state. This is best obtained by the following procedure: 1. Two hours before operation, one capsule of phenobarbital sodium or sodium amylal is administered. 2. One hour before, one-fourth grain (0.016 Gm.) of morphine and a second capsule of phenobarbital sodium or sodium amylal are given. 3. One-half hour before, 1 cc. of a 2 per cent solution of butyn is instilled into the pharynx with a curved cannula. This is swallowed, causing a slight algesia. 4. Fifteen minutes before, the lateral wall of the pharynx is swabbed on both sides with a 10 per cent solution of cocaine by holding the swab against the lateral wall for ten or fifteen seconds on each side in the region of the recurrent laryngeal nerve. This application should be made three times at intervals of five minutes. As the position of the patient is changed with the advancing of the instrument, each must be controlled by a trained assistant to synchronize with the operator's movements of the instrument. Several times during the introduction it may be necessary to aspirate fluid, as the field must be kept clean. As soon as the gastroscope enters the stomach, the light carrier is removed and the lens system with light for illuminating the stomach is put into place. This fits air tight, permitting the stomach to be inflated, which should be done carefully under guidance of the operator's eye. No more air should be introduced than is required to push the stomach away from the window and obtain a clear view. An occasional bulbful or two of air will keep the mucous membrane under clear observation. A good method to prevent overinflation is to have an assistant place a hand over the epigastrium. The whole procedure of introduction and inspection should be completed in from ten to fifteen minutes. While there is some discomfort due to the position of the patient, with proper skill and experience it should not be a painful procedure, and this assurance will do much to enlist the patient's confidence.

**Cardiovascular Syphilis.**—The incidence of syphilis in 1,000 consecutive ambulatory patients whom Newman has seen in the private practice of cardiology was 3.4 per cent, and of cardiovascular syphilis 3.2 per cent. Of these 43.6 per cent had simple aortitis, 34.4 per cent aortic insufficiency and 22 per cent aneurysm. The blood Wassermann or Kahn reaction was positive in 87.5 per cent and negative in 12.5 per cent. For practical purposes a diagnosis of cardiovascular syphilis is justifiable in any patient with a sacular aortic aneurysm or in any patient more than 40 years of age with aortic insufficiency and a positive Wassermann reaction, provided there is no stenosis of any valve or definite history of rheumatic fever; or in any patient with a positive Wassermann or Kahn reaction, especially if he is less than 50 years of age and complains of substernal pain or dyspnea on exertion, in whom the roentgenogram shows an aortic shadow wider than one would expect for his age or blood pressure, or who has a localized dilatation of the ascending aorta, often best seen fluoroscopically in the left anterior oblique position. Adequate treatment of early syphilis is extremely effective in the prevention of clinical cardiovascular syphilis. In the presence of established cardiovascular syphilis the preponderance of evidence (although not strictly applicable to statistical analysis) is in favor of the beneficial effect of specific therapy, not only with the heavy metals and iodide but also with arsenicals in suitable dosage. The earlier in the course of the disease antisyphilitic therapy is begun, particularly before the onset of aneurysm or aortic insufficiency, the better are the chances of improvement.

p. 329.

**Spread of Tularemia Through Water.**—Having studied an outbreak of tularemia in 1935, Karpoff and Antonoff were able to prove by exhaustive evidence that water was the mode of spread of the disease. An epidemic broke out among people who were occupied in haymowing. In a week's time nearly all the workers had been taken ill, with the exception of one group of mowers who worked on a plot near by. The disease appeared in from two to eight days after the people came to the meadow lands. In the meadows on which the epidemic

broke out there are four eminences, divided by valleys, through which flow a river and three brooks. One group of mowers used the water of the river for drinking and in this group there did not occur a single case of illness; the other mowers, among whom the illness rate attained 100 per cent, used the water of one of the brooks, which at the time in question was running freely. Questioning of the patients showed that near the brook out of which they took their drinking water, they had seen, as they said, some water rats and had killed one of them, but all the people who had been in the fields declared these to be but isolated examples. Besides the rats a few field mice had been observed. In experiments in which the rôle of water in spreading the infection was tested, 100 per cent of the guinea-pigs infected with the water died and their organs showed characteristic pathologic-anatomic changes. From the organs of all these guinea-pigs, cultures of Bacterium tularensis were obtained. The cultures that were isolated from water did not differ with regard to virulence from those that were isolated from the suppurated lymph glands of the patients. When these cultures were tested on guinea-pigs, death followed in 100 per cent of cases and the organs showed changes characteristic of tularemic infection. In the outbreak in question the ports of entry were the tonsils, the mouth, the mucosa and the conjunctiva. The anaginal form was predominating and the typhoid form came next, while a number of patients showed the glandular-ocular form of illness.

**Rapid Flocculation Method for Diagnosis of Syphilis.**—Since the committee appointed by the United States Public Health Service, on the evaluation of serodiagnostic tests for syphilis in the United States, concluded its first report in 1935, Rytz has modified the rapid flocculation method, as first applied to spinal fluid (original abstracted in THE JOURNAL, May 25, 1935, p. 1937). The modified technic renders the test for spinal fluid more sensitive. A strongly positive reaction consists of large, irregular flocculate particles in a crystal-clear fluid. A weakly positive test shows smaller flocculate particles in a slightly hazy fluid. The negative reactions show a hazy fluid with unflocculated emulsion particles. He has compared 185 reactions by this method with the Wassermann test as

carried out in his laboratory. This flocculation method showed fifty-nine positive reactions against thirty-six positive Wassermann tests on the same samples. Of the fifty-nine positive cases by the flocculation method, forty-seven showed positive blood tests, and eight patients with negative blood tests had a definite syphilitic history. Two patients with some symptoms of neurosyphilis remain, at this time, unverified by clinicians.

### Journal of Nervous and Mental Disease, New York

84: 373-496 (Oct.) 1936

- First Fifty Years of the Philadelphia Neurological Society. W. G. Spiller, Philadelphia.—p. 373.

Hoffmann Sign: Its Incidence in University Students. D. H. Echols, Ann Arbor, Mich.—p. 427.

**Brain Trauma.**—Winkelman and Eckel studied five cases of the posttraumatic state for a period of from four months to four years. Clinically the patients showed personality change and convulsive seizures as the most common manifestations. Focalizing signs and symptoms were present in only one case. Activation of a preexisting syphilitic process resulted in the formation of a gumma at the point of trauma. Histopathologically the patients showed focal lesions of hemorrhage and softening, with scattered petechial lesions of the same sort. The changes in the brain in general were to be attributed to the original concussion with the secondary changes due to anoxemia from increased intracranial pressure. These involved the ganglion cells and blood vessels in addition to a universal glial overgrowth. Adhesions of the pia-arachnoid to the cortex and to the dura were present in nearly all the cases. In one case an abscess developed at the point of impact in a patient with an old middle ear disease, with generalized convulsions occurring seven days after injury, although intracranial pressure signs did not occur until three years later.

Nelson, Washington, D. C.; D. J. Barnes and Florence A. Browne, Detroit, and Rachel M. Jeness, Washington, D. C.—p. 355.

**Mediterranean Disease—Thalassemia.**—Four years ago, Whipple and Bradford reported the clinical and necropsy features in a typical case of Mediterranean disease. As the pigment abnormalities there described had not been noted in other published reports, they could not stress their importance. They now report three more cases with complete necropsy reports. They have had opportunity to study certain organ tissues from two other cases. All this material gives them reasonable security in their belief that the pigment deposits are just as characteristic of this disease complex as are any other factors. The disease presents a uniform clinical picture consisting of a progressive anemia beginning usually during the first two years of life and terminating in death in most instances before adolescence. The blood picture, though not distinctive, is uniform and is characterized by marked irregularity in the size and shape of the red cell, fragmentation and erythroblastosis. All stages of erythropoiesis may be seen

in the peripheral blood. The hemoglobin distribution within the matured red cell may be very irregular. After splenectomy, showers of nucleated red cells always occur. Definite retardation of growth results. As the disease progresses, the typical mongoloid features develop, probably because of bone changes. Enlargement of the spleen is proportionally greater than that of the liver, but, when the former is removed, the latter seems to increase in size. To this group of clinical features the addition of the abnormalities that occur in the bones, the unusual pigment disturbances, and the racial and familial distribution complete a characteristic syndrome. Therefore the disease is due to some racial, inherited defect which is responsible for the abnormalities of the hematopoietic tissues (of the order of pernicious anemia), the bone changes (of the order of acromegaly) and the pigment abnormalities (virtually identical with hemochromatosis). This suggests a deficiency state that may be remediable when completely understood and gives adequate grounds for a variety of therapeutic tests. The anemia may be classified as microcytic and hypochromic. The following therapeutic measures failed to modify the clinical picture: blood transfusions, plasma and cell extracts, primary or secondary anemia liver extracts, fetal liver extract, spleen extract, raw pancreas, adrenal cortex extract, estrogenic substance, vitamin B<sub>1</sub> concentrate, iron and copper.

**Meningococcus Carriers.**—Silverthorne investigated the carrier rate in a noncontact population and the bactericidal property of the blood of normal persons and of noncontact carriers against various strains of meningococci. A total of 1,227 swabs were taken monthly from sixty-three normal healthy adults over a period of two years; 19.8 per cent of these were positive for the meningococcus. On these monthly examinations the number of positive individuals varied from 16 to 28 per cent. No less than 41 per cent of the group of sixty-three were positive at one time or another during the period of study; eleven were persistent, thirteen intermittent and two transient carriers. Eleven noncontact carrier strains were examined by the bactericidal and mouse-mucin tests; three of these strains were found to be virulent and eight were found to be avirulent. Carriers of the meningococcus possess bactericidal power in their blood to their respective strains, whether these strains are virulent or avirulent. Also, samples of blood from carriers possess bactericidal power to certain virulent cerebrospinal fluid strains. The determination of the virulence of strains of meningococci by means of the mouse-mucin and bactericidal tests may serve as a useful means of selecting strains for the preparation of therapeutic serum.

### Laryngoscope, St. Louis

\*Effect of Intranasal Phenol Application in Hay Fever: Quantitatively Studied by New Intranasal Swab Test with Pollen Extracts. F. Vistreich, New York.—p. 717.

**Intranasal Phenol Application in Hay Fever.**—Vistreich observed the effect of intranasal phenol application in twenty-eight consecutive cases of early and late hay fever. The treatment is not followed by stormy reaction or long convalescence. From 90 to 100 per cent relief was obtained in 75 per cent of the cases, from 75 to 90 per cent relief in 8.3 per cent, from 50 to 75 per cent relief in 12.5 per cent and no relief in 4.2 per cent. By intranasal swab tests with serial dilutions of pollen extracts it was proved that this treatment produces an actual decrease in the sensitivity of the nasal mucosa to pollen. By periodic testing it has been found that this state of relative insensitiveness is not permanent. Its average duration in the present group of cases was approximately from seven to eight weeks.

**Electrosurgical Treatment of Cervical Lacerations.**—Barrett finds that electrosurgical diathermy with the Hyams technic, the Cherry Ende technic or the simple ball coagulation technic is suitable for the treatment of the majority of the cervical lacerations, erosions and endocervicitis. The method is not free from danger. Too extensive destruction of tissue may lead to primary or secondary hemorrhages. Deep destruction of tissue high in the cervical canal, especially if there has been carbonization, tends to heal with excess fibrous tissue with its consequent impairment of drainage, stenosis, sterility and dystocia. Curtis has shown that stenosis and cavitation in the upper cervix with secondary infection and lack of drainage is a frequent cause of irritant leukorrhea, epithelial metaplasia and leukoplakia. A thorough dilation of the cervix is indicated if the treatment is to be carried above the level of the lower third of the canal. The dilation should be repeated after healing occurs if there is any sign of constriction. Carbonization and deep destruction of tissue should be avoided. Electrosurgical diathermy is contraindicated in the presence of an active or latent pelvic infection.

**Cancer of the Breast.**—Simmons and his co-workers report the five year end results of 159 cases of cancer of the breast treated by radical operation at the Massachusetts General Hospital during the three years 1927, 1928 and 1929. There were 43.4 per cent of five year cures following radical operation. Of the fifty-eight persons in whom the disease was limited to the breast, forty-four were living without evidence of recurrence from five to seven years after operation. Of the 101 patients in whom the axillary glands were involved, twenty-five were living without evidence of disease from five to seven years after operation. The prognosis was found to depend more on the extent of the disease and the pathologic index of the malignant condition of the tumor than on any other factors. This coincides with the observations in the former groups studied. The median duration of the disease before operation of the cases without axillary involvement was three months. The median duration with axillary involvement was six months. The importance of early diagnosis and treatment is shown by comparing results of operation in these two groups. Preopera-

tive roentgen treatment was given to a certain number of these patients. It had no effect on the results when the cases were placed in comparable groups. The dosage was much less than that advocated at the present time but was similar to that given at other institutions during the period under investigation.

**Asbestosis.**—Shull defines asbestosis as a disease of the lungs caused by the inhalation of asbestos dust and fiber. It is classified as a pneumoconiosis and is characterized roentgenologically by an early interstitial fibrosis with progression into a terminal diffuse fibrosis. As the disease progresses there develops a filmy, hazy appearance of the lung, which has been aptly described as a "ground-glass appearance." The right side of the heart is frequently enlarged in the moderately advanced cases, and it is a common observation in the markedly advanced cases. Another finding characteristic of this disease is the presence of peculiar golden colored, crustation-like bodies in the lungs of these patients. Clinically, the most striking symptom is undoubtedly dyspnea. During the latter part of 1934 the author examined the chests of seventy-one of 100 workers who had been dismissed from local asbestos plants. All had undergone physical examination before they were referred for roentgenologic study and were found to be physically disabled. The average age was 34.4 years and the time of exposure varied from sixteen months to twenty-one years. In eight recognized cases of tuberculosis (11.3 per cent) in the entire series the degree of infiltration was only slight to moderately advanced and one or both upper lobes were involved. Only two cases appeared active. Since these examinations were made, five patients have died. Of the remaining sixty-six patients, twenty-one have been reexamined recently. In studying the original and follow-up roentgenograms of the series and contrasting them with a number of plates of other types of pneumoconiosis, it has been possible to make certain observations which seem to be peculiar to this group of asbestosis cases as a whole. Furthermore, it was obvious that a classification could be effected. Since the one constant feature of all these cases is unquestionably the diffuse fibrosis, this sign was taken as the "yard stick" in compiling such a classification (slightly, moderately and markedly advanced cases). Of sixteen slightly, thirty-five moderately and twenty markedly advanced cases, 37.5, 62.8 and 95 per cent respectively showed a right-sided hypertrophy, 0, 28.6 and 45 per cent pericardial and pleural thickening, 12.5, 48.6 and 80 per cent a high left diaphragm and 6.3, 65.7 and 95 per cent an emphysematous type of chest.

\*Cervical Gland Tuberculosis: Case Against Surgery. B. C. Thompson.—p. 584.

Homework. W. Brockbank.—p. 587.

**Hypochromic Anemias of Pregnancy.**—Fullerton found that the average hemoglobin levels of poor women fell during pregnancy up to the thirty-seventh week of gestation and then rose slightly before delivery. A rise in the hemoglobin level occurred from forty-eight hours post partum to from six to eleven months after delivery. Even in women of the poor classes the transference of iron from the mother to the uterus and its contents is compensated wholly or to a large extent by dietary iron. In cases in which this demand exceeds the retention of dietary iron, the degree of maternal iron deficiency which results is only slight. When hypochromic anemia in pregnancy is marked, anemia has probably existed before the pregnancy but has been made more apparent by physiologic hydremia. Therefore the conception that uncomplicated pregnancy frequently produces a severe degree of hypochromic anemia should be discarded. The blood loss at parturition varies greatly in degree and often produces severe hypochromic anemia.

**Cervical Gland Tuberculosis.**—Observation of forty-four patients led Thompson to conclude that tuberculosis of the cervical glands is seldom, if ever, completely removed by surgical means, and that so-called radical excision is in practice usually a partial operation. This partial excision can be justified only if proved by results to be superior to other methods of treatment. The high rate of local recurrence and the degree of permanent disfigurement due to cicatrization found in this series of cases indicates the reverse. It is also shown from the figures of other observers that the operation does not prevent the subsequent development of pulmonary tuberculosis. Additional disadvantages are the inconvenience caused to the patient by hospitalization, the frequent necessity for repeated operations, and the risk of paresis from nerve injury. It is held that conservative treatment has none of these disadvantages and ultimately produces results in every way more satisfactory.

Treatment of Appendicitis. R. A. Stoney.—p. 591.

**Late Ether Convulsions.**—Smith illustrates the close connection between what are called "ether convulsions" and heat hyperpyrexia. The literature of both subjects indicates that ether convulsions and heat hyperpyrexia are identical. The phenomena of postoperative thyroid crises may be a manifestation of heat effects in a disordered heat regulating mechanism. The treatment adopted for these crises follows closely that of heat hyperpyrexia. Some cases of death from status lymphaticus may have a similar origin. Hadfield remarked (1928) that heat was the sole common factor in all the ether convulsion cases which he summarized. The most important prophylactic measure would be the recognition of the fact, generally, that heat hyperpyrexia can occur in the modern operating room in temperate countries, a sense of proportion being maintained, as the reported cases occur in only 1 in 5,000 administrations. Surgical patients in hot weather periods should be encouraged to drink large quantities of liquids, and their urine should be kept alkaline. There should be a sufficiency of salt in the diet.

The rectal temperature and pulse rate of patients for operation should be recorded prominently on their charts. In hot weather the substitution of scopolamine for preoperative atropine should be considered. Potential subjects of heat hyperpyrexia requiring immediate operation should have their knee jerks tested first and be operated on in a cool room; excessive covering of the body by rubber sheetings should be avoided and the head slightly raised if possible. Anesthesia could be induced and maintained with the head resting on an ice bag or an ice bag in close contact with the carotid vessels. Induction with chloroform or a mixture should be considered. The acute case should be diagnosed early by the taking of the rectal temperature and treated on general heat hyperpyrexial lines modified by the circumstances present. Pentobarbital sodium or *n*-methyl-cyclohexenyl methylmalonyl-urea could be given for the convulsions. After-treatment is extremely important, as recurrences of hyperpyrexia are frequent and the cases must be watched carefully for some days.

**Cirrhosis of Liver.**—In reviewing a series of fifty-four cases of cirrhosis of the liver Wang found that thirty-two of the cases (59.3 per cent) occurred in the fourth and fifth decades of life. The disease occurs largely in the working classes, especially in farmers. Alcohol, syphilis and malaria may be considered etiologic factors in its production. The galactose tolerance test, detection of urobilin in urine and the van den Bergh reaction were valuable for detecting and estimating the amount of liver derangement. Ten of twenty-seven fractional gastric analyses (37 per cent) demonstrated achlorhydria. Nearly all patients had leukopenia and half had anemia. Only five cases (9.2 per cent) showed hematemesis. Symptoms of gastric disorder were present in all but two of the cases; roughly one half of the patients gave a history of gastric disturbance before the onset of ascites. Enlargement of the liver was found in nine cases (16.6 per cent), enlargement of the spleen in eighteen (33.3 per cent) and thirty-four (63 per cent) presented jaundice.

\*Partial Icterus. N. Fiessinger and G. Boudin.—p. 1259.

**Partial Icterus.**—The type of icterus which is characterized by localization in one segment of the body, most often in the upper portion, is discussed by Fiessinger and Boudin. This localization, when it occurs, is only the consequence of an edematous infiltration of dependent portions. The first patient was a woman with the common type of Laënnec's cirrhosis. When this patient was first observed the icterus was generalized, but, as ascites and edema developed, the location of the icterus became the reverse of that of the edema. This local washing of the icterus could be experimentally reproduced by the authors by the injection of physiologic solution of sodium chloride into the subcutaneous tissue stained with the characteristic icterus color. The interest of this phenomenon of partial icterus seems to be purely symptomatic. The mechanism is simply the washing away of icterus by edematous infiltration of certain regions. This result, however, is aided by the fact that edema is produced at a stage when the bilirubinemia is decreasing and by the simple dilution of the bilirubin by the excess of fluid.

\*Local Reactions of Capillaries to Histamine and Acetylcholine in Course of Different Varieties of Hypertension. E. Dicker.—p. 1454.

**Reactions of Capillaries to Histamine in Hypertension.**—Dicker studied the local capillary reactions in different varieties of hypertension under the influence of histamine and acetylcholine. His method of observation differed from that of Ernste and Snyder only in the fact that he calculated simultaneously in the same person the surface of the erythema produced by the intradermal injection of 0.05 cc. of a 1:1,000 solution of histamine and that produced by the intradermal injection of a drop of a 1:100 solution of acetylcholine. As a result of his studies he concluded that in the normal state the extent of the erythema following the intradermal injection of histamine or acetylcholine attains a mean of 25 and 17 sq. cm. respectively. It varies from one subject to another but in the same person preserves a satisfactory consistency in different examinations. In patients with essential hypertension and arteriosclerotic hypertension the surface area of the erythema produced does not differ from that of normal subjects. In nephritic hypertension, malignant hypertension and malignant nephrosclerosis, the erythema produced by the injection of these substances is slightly increased but the surface area is strongly reduced. In the course of certain infections that may produce acute nephritis, such as scarlet fever and streptococcal tonsillitis, the intensity and area of reaction to histamine and acetylcholine are reduced during the period of resultant hypertension. These facts, the author believes, constitute an important argument in favor of the conception which attributes the development of essential hypertension and malignant hypertension to two distinct mechanisms. The latter is probably associated with a state of constriction of the peripheral vessels.

- \*Skin Reactions to Tuberculin in Children from Birth to the Age of 2 Years. P. Nobécourt and S. B. Briskas.—p. 1465.  
Artificial Production of Thyroid Hyperplasia. H. Zondek.—p. 1469.

**Skin Reactions to Tuberculin in Small Children.**—Nobécourt and Briskas studied the tuberculin reactions of 6,607 nurslings less than 2 years of age. These tests were performed over a period of fifteen years, from 1921 to 1935 inclusive. Terminal states of anergy were encountered in 8.9 per cent of the tuberculous patients. Furthermore, almost all the cases of tuberculosis in this age group were in an active state. The number of infants infected with tuberculosis was small during the first months but increased with age. The number of patients

with active tuberculosis was roughly parallel. During the second year the proportion of infected infants who had had inactive tuberculosis was much greater than during the first year of life. Also during the second year infected girls more often than boys had active tuberculosis. The latter fact may be explained perhaps on the basis of certain predispositions.

Technic of True Pleural Endoscopy Before Cauterization of Adhesions. M. O. Mistal.—p. 687.

**Tuberculous Infection in Country Children.**—In 1935 Rochat studied 450 students by means of the roentgen ray and the Pirquet reaction. The Pirquet test was found negative in 80 per cent of the subjects from 12 to 16 years of age and in 90 per cent of the younger children. These facts have a considerable diagnostic importance not only for the little ones but also for the older children. A year later the children with positive tuberculin tests reacted in an identical fashion. The papule showed the same aspect as in the previous test. Poor hygiene conditions do not constitute the determining factor in the dissemination of tuberculosis. Tuberculosis is a disease of wretched lodgings only if there are also patients with the disease present. Of sixty children with positive reactions there were only ten instances in which the source of the contagion was known. The latter fact suggests the probability that the infection of the children took place most often by carriers of the germs who were in apparent good health.

\*Hydrophilia in Tissues and in Blood in Cholecystitis and Catarrhal Jaundice. E. Poli.—p. 641.

**Hydrophilia in Tissues and Blood in Cholecystitis.**—Poli calls attention to the relation that exists between liver diseases and disturbances of the water metabolism. The author found that in patients suffering from cholecystitis or from catarrhal jaundice the water is retained by the blood and the tissues. The factors that cause the tendency of blood and tissues to water retention or actual hydrophilia in these patients are stasis of the portal circulation, defective elaboration of bile salts, dysfunction of the liver in controlling the balance of the organic electrolytes (because of a defective chemistry of the bile secretion) and changes in the amount of lipids contained in the blood serum. These factors, which become apparent in the course of cholecystitis and catarrhal jaundice, are capable of disturbing the organic water metabolism.

Dermo-Epidermal Grafts: Technic and Results. D. Clemente.—p. 1861.  
Hemotherapy. S. Colaneri.—p. 1864.

**Amenorrhea in Diabetes.**—Bompiani says that amenorrhea and the development of involutive changes of the genitalia in diabetes are secondary to alterations of the anterior lobe of the hypophysis and of the diencephalon. By reviewing clinical and experimental reports in the literature it is obvious that the anterior lobe of the hypophysis and the hypothalamic nuclei are the structures by which the sugar metabolism and the phenomena of the uterine-ovarian cycle are controlled. On the one hand, hypophyseal syndromes are frequently associated with changes in the sexual function and alterations of the genitalia and, on the other, anatomic alterations of the hypophysis and of the diencephalon are often found in diabetes of definite insular origin. According to the author, the hypophyseal-hypothalamic pathogenic mechanism of amenorrhea explains the frequent production of amenorrhea preceding diabetes and the

reestablishment of the uterine-ovarian cycle and the regaining of fecundity in women suffering from amenorrhea and treated with insulin.

**Generalized Osteopathy with Symmetrical Striae.**—The skeletal disease to which Dall'Acqua and his associates refer develops in persons beyond the second decade of life. It is progressive and fails to respond to treatment. The characteristics of the disease are pain in the bones, disturbances in gait and a peculiar multiple symmetrical involvement of the skeleton. The roentgen examination of long and flat bones shows, in several of them, multiple symmetrical transverse bands (pseudofractures) of increased transparency, about 3 or 4 mm. long, which involve the bone superficially or in its entire depth. The pseudofractures do not cause separation and displacement of the fragments. The condition is the result of local reabsorption of the bone. It is different from Looser's zones of decalcification. The bands are located at the epiphysis and the metaphysis rather than at the diaphysis. At the site of the pseudofracture none or only a slight periostic reaction takes place. The pseudofractures occur simultaneously in corresponding bones on the two sides of the skeleton, but the size and exact location of the fractures may be different. During the evolution of the disease the viscera remain normal, as proved by clinical and roentgen examinations. The blood phosphatases are increased. A differential diagnosis is made by the authors between the disease and rickets, osteomalacia, osteogenesis imperfecta and multiple myeloma of the bones. The authors conclude that the disease is rare and probably due to nervous and vascular disturbances. Their case is the third reported in the literature.

**Thrombo-Angiitis Obliterans.**—Yanovsky names thrombo-angiitis obliterans (of Buerger's type) neuro-angiitis obliterans, indicating involvement of the sympathetic nerves and blood vessels in the pathologic process. The condition generally occurs in the blood vessels of the extremities in patients ranging in age from 20 to 35 years with an emotional, psychic and neurovascular predisposition. The early neurovascular lesion consists in inflammation and fibrosis of the adventitia and its sympathetic fibers. Degeneration of the sympathetic fibers and disorganization of the vascular layers from the adventitia to the intima and endothelial alterations follow. The lumen of the blood vessels is occluded by a thrombus (which is secondary to the endothelial changes) or by the propagation of fibrosis from the outer to the inner layers of the vessels. In normal peripheral blood vessels, sympathetic fibers exist only in the adventitia. The presence of sympathetic fibers in the inner layers of the blood vessels in thrombo-angiitis obliterans is due to the inward propagation of the lesion and disorganization of the vascular tissues. Certain nervous oval cells which can be seen at the adventitia of the blood vessels are peripheral cells and not multipolar ganglions. Probably they are concerned in maintaining the tonus of the local vessels. The formation of a thrombus is not specific in thrombo-angiitis obliterans. It may

exist in certain vascular diseases with an etiopathogenesis different from that of thrombo-angiitis obliterans. The endocrine glands have a direct action on the sympathetic nerves of the blood vessels. Nervous lesions develop in certain chronic forms of thrombo-angiitis obliterans. Arteriosclerosis is the third stage in the evolution of the disease. It may be followed by calcification of the vascular walls. Typical clinical forms of thrombo-angiitis obliterans are biologically and anatomopathologically different from syphilis. The administration of anti-syphilitic treatment does not induce changes in the evolution of the disease. The condition can be easily mistaken because of the fact that the intravascular alterations of chronic syphilitic arteritis are similar to the occlusion in thrombo-angiitis obliterans.

Plastic Repair of Roof of Acetabulum in Coxa Valga Luxans and in Irreducible Congenital Luxation of Hip. J. Baumann.—p. 1182.

**Wandering Epiphysis on Head of Femur.**—Mau stresses that, if young persons, particularly boys, at about the age of puberty complain of pains in the hips, fatigue and occasional limping, the physician should take into consideration that a beginning loosening and wandering of the epiphysis might exist. It is important to recognize the beginning slipping of the epiphysis of the femoral head first backward and then downward, because the complete development of the adolescent form of coxa vara, the adduction contracture in connection with the position of outward rotation, is practically irreparable and usually leads to a deforming arthrosis of the hip, which may result in early invalidism. After discussing the normal position of the epiphysis of the femoral head and after pointing out that there are definite constitutional types that are especially predisposed to the development of adolescent coxa vara, the author discusses the pathogenic mechanism, pointing out among other factors that investigators have detected signs of softening in the epiphyseal cleft of the patients with this disorder. Moreover, in a number of cases the anamnesis reveals a mild trauma. He discusses the symptomatology and diagnosis of this condition and says that, once the "wandering" of the head begins and the femoral neck starts to turn forward, the patients generally complain of pains in the knee, and the first signs of inhibited movement in the hip joint appear. A comparison of the movements of the two hip joints usually reveals that the inward rotation as well as the outward movements of the diseased hip are restricted. A shortening of the leg is usually not perceptible during the beginning stages of the disorder, but a slight emaciation of the musculature of the thigh often appears quite early. These comparisons between the two sides are of course without value if both sides are involved. Roentgenoscopy is of great help, particularly in the obscure cases. In discussing the method of roentgenography, the author stresses that the roentgenogram made in the sagittal direction is especially valuable, in that it reveals a certain loosening and widening of the epiphyseal line. The sagittal exposure should be supplemented by a frontal one. Moreover, a pelvic roentgenogram should be taken in Lauenstein's position, for it permits a frontal exposure of the neck of the femur. Once the beginning of the epiphyseal wandering has been recognized, the author applies, without previous redressment maneuvers, a plaster-of-paris cast to the pelvic region. After four weeks he changes to a mild extension and begins with careful exercises in bed and soon thereafter with walking exercises with the aid of a splint, splinting being continued for several months. With this treatment applied to the early recognized deformity, the author obtained complete cure. He describes several cases and mentions as another important roentgenologic sign a reduction in the vertical diameter of the spherical cap of the femoral head, which appears also on the roentgenogram that is made in

agittal exposure. He concludes his report by stressing the necessity of immediate treatment after the recognition of the early signs.

**Treatment of Clubfoot.**—According to Gardemin, the aim of the treatment of congenital clubfoot is the production not only of a normal external shape of the foot but also of a normal shape of the skeletal system. Only after this has been accomplished is it permissible to talk of a morphologic and functional cure. Before discussing the treatment as such, the author discusses the theoretical possibilities and requirements that must be fulfilled to accomplish this aim. He shows that it is important to treat the clubfoot as early as possible. The treatment of clubfoot, no matter at what age, follows the same principles, but the technic differs. The correction of the abnormal position does not take place in the bandage but is accomplished by molding redressements according to the method of Lorenz. The bandage is applied to preserve the correction that has been obtained. In treating clubfoot in a nursing, the author performs manual redressements every day for two weeks. He fixes the region of the ankle joint with the thumb and forefinger or with the closed fist of the one hand, so as to avoid fracture of the thin tibia and fibula. The other hand grasps the heel or the anterior portion of the foot and attempts to free the bones of the tarsus from their confined position by repeated pressure. The author does not consider it advisable to correct the malformation in one session and regards the gradual loosening of the contracted ligamentous apparatus the better method. He stresses that, in order to avoid injuries, the redressements should be done only by some one who thoroughly understands the method. After the manual redressements have effected correction, the result is fixed by means of a plaster-of-paris cast. In older children and in adults, manual correction is usually no longer possible and appliances of various types are used. The author uses the apparatus of Stille-Lorenz and of Alsberg, the Phelps-Gocht clamp and König's wedge. He does not strive to overcome the deformity completely in one session but is at first satisfied with a mild degree of correction. A plaster-of-paris cast is put on after every redressement and is left on for four weeks. The tensions within the foot may not exceed a moderate degree, or the resulting trophic changes may cause serious sequels. If redressements do not have the desired results, surgical interventions must be tried. To insure good permanent results, a careful after-treatment is essential. For a while the foot must be held in the corrected position by means of orthopedic devices, for there is danger of relapse if this is not done.

**Dinitrophenol Derivatives.**—In a review of the history of dinitrophenol derivatives, Handovsky points out that the attention of toxicologists has been directed to these substances because they have been used for the coloring (yellow and orange-red) of foods for approximately five decades. As early as 1885 it was found in animal experiments that the ingestion of these substances may result in polypnea and increased temperature. The first knowledge about the localization of the action of these substances was obtained through investigations on the toxicology of 2,4-dinitrophenol, large quantities of which were used in French gunpowder factories during the World War. These investigations were carried on because of numerous cases of poisoning among the workers of these factories. In later years the studies were continued and, as regards the localization of the action of the dinitrophenol derivatives, it was found that in several species of animals there was a considerable increase in loss of heat by polypnea and sweats, a rise in temperature and an enormous increase of the metabolism, of the loss of glycogen and of the oxygen consumption. Later experiments revealed that the dinitrophenol derivatives have no central

point of attack and that the heat production effected by dinitrophenol takes place in the muscle cells. Thus the action of these substances is a cellular one. The author cites the studies of other investigators and then states that he himself was able to prove that the dinitrophenol derivatives are capable of stimulating the dehydrogenation processes. He describes and discusses experiments from the outcome of which he concludes that the dinitrophenol derivatives increase the metabolism and the temperature by stimulating the combustion of substances with a high combustion heat. These substances are formed in the organism even under normal conditions, but ordinarily their caloric value is not being utilized. Because the dinitrophenol derivatives facilitate the combustion of body materials, attempts were made to use them in the treatment of obesity. However, it was discovered that medication with dinitrophenol involves many dangers and so the therapeutic use was discouraged. Nevertheless, the author thinks that experimental therapy should make further studies on the dinitrophenol derivatives. It should be investigated whether their capacity to prevent the division of cells might be of value in the treatment of cancer. Moreover, they might prove helpful in irradiation and in fever therapy. In the treatment of obesity the combination of subtherapeutic doses may prove helpful.

**Carcinoma of Small Intestine with Chronic Invagination.**—Knirsch, after pointing out that cancerous degeneration of the small intestine is not as rare as was formerly believed and after citing statistics about the incidence of this form of cancer, reports a case of primary cancer of the small intestine, which is noteworthy because the cancer resulted in chronic invagination. Moreover, in spite of the fact that the patient had diabetes and a myocardial defect, the invagination tumor could be radically removed in a single operation and the patient could be discharged as cured.

- \*Congenital Disposition to Malignant Tumors. N. Pende.—p. 793.
- Action of "Pituspasmine" and of Parturient Women's Serum on Uterine Muscles. S. Boguszewski.—p. 797.

**Congenital Disposition to Malignant Tumors.**—Pende says that in malignant tumors there is a dynamic-humoral condition of the entire body or of special organs which predisposes the tissues to the development of malignant tumors under the influence of external causes but which alone would not be sufficient for the development of a tumor. Experiments on both human beings and animals disclose various causes, but the natural cause has not been proved. Cancer is a constitutional disease and local treatment by surgery or other means is a mistake. He points out that the Irish and the Basque are especially predisposed to cancer, while the Negro and the Indian are seldom affected by malignant tumors, and he feels that the amount of intake of cholesterol may have some influence in the matter. However, he thinks that it is unwise at this time to give any cause for the predisposition to cancer for the different races. Heredity is an important factor, as is sex, since women are more often affected than men. Age should also be taken into consideration. Finally, there does not seem to be any doubt that there must be some relationship between the various endocrine glands and cancer, such as between cancer of the stomach, the skin and the intestine and overactivity of the thyroid and vagotomy and tumors of the female organs, with hyperactivity of the anterior part of the hypophysis.

- Method of Determining Functional Capacity of Cardiovascular System in Pulmonary Tuberculosis. A. E. Rabukhin, A. I. Gurevich and L. A. Spivak.—p. 1246.

**Pathologic Anatomy of Dust Tuberculosis.**—On the basis of an investigation of 2,600 miners of the Donbass region, Moschkovskiy concludes that pneumoconiosis exists as an inde-

pendent disease entity. Clinical, roentgenologic and biologic data obtained over a long period demonstrated that a preponderant majority of cases of pneumoconiosis were not tuberculous. He feels justified in dividing his cases into those of pneumoconiosis caused exclusively by dust, and those of conio-tuberculosis in which both factors exist—dust and tuberculous infection. Clinical, pathologic and histologic studies of his cases fail to support the hypothesis that the nonspecific fibrosis resulting from coniosis can act as a defensive mechanism against a tuberculous infection. Postmortem examinations of several of his cases demonstrate the possibility of development of a grave tuberculous process with caseous tissue reaction on a basis of intensive coniotic fibrosis. This concept of a mechanical blockade is further contradicted by the localization of tuberculous caseating foci in the center of coniotic areas. Peribronchial and perivascular distribution of purely coniotic areas without elements of tuberculous infection was likewise found. This testifies to pneumoconiosis as an independent process. The pneumoconiosis node differs from the tuberculous focus by the absence of lime and central necrosis. Tubercle bacilli in sputum are less frequent in coniotuberculosis even in the presence of considerable destruction of the pulmonary tissue, probably because of limited connection between cavities and the bronchi. Coal pigment spreads by way of lymph and blood and in advanced cases may be seen deposited in the various viscera, particularly the liver and spleen.

\*Treatment of Lichen Ruber Planus (Especially with Roentgen Irradiation and with Injections of Bismuth): Comparative Investigation on Results. C. E. Sonck.—p. 702.

**Bone Marrow in Hemolytic Jaundice.**—In Tötterman's case of hemolytic jaundice, the patient being a woman aged 33, treated in 1935, liver therapy proved ineffective, succeeding treatment with arsenic for several weeks was without marked effect, but splenectomy was followed by rapid improvement. The first sternal puncture, shortly after admission, showed 1,893 nucleated red blood corpuscles per 400 white corpuscles; there were 1,217 normoblasts, 470 macroblasts, twenty-two normoblasts with mitosis, 110 normoblasts with amitosis, twenty macroblasts with mitosis and one mature megaloblast, together with fifty-three large cells with nongranulated basophile plasma and a round, finely reticulated nucleus with two or three nucleoli. As in the blood, the number of reticulocytes in the bone marrow was 0.6 per cent. On the second sternal puncture, about three weeks later, there were 259 normoblasts, sixty macroblasts, two normoblasts with mitosis, three macroblasts with mitosis, and seven promegaloblasts. A third sternal puncture, seven months after splenectomy, when the blood had been normal for a considerable time, except for the continued lowered resistance and microcytosis, revealed a normal white blood picture with ninety-nine normoblasts, five macroblasts, five macroblasts with mitosis and one uncertain promegaloblast to each 400 white cells, affording further proof of the effectiveness of splenectomy in hemolytic jaundice. In this case both the mitotic and particularly the amitotic erythropoiesis in the bone marrow was more pronounced than in any case of pernicious anemia. The patient was not achylic and apparently had all of Castle's "intrinsic factor," which protected her against a disturbance in the maturing process of the erythroblasts, so that mainly normoblasts and normocytes developed.

**Treatment of Lichen Ruber Planus.**—Sonck states that of seventy-three patients presenting lichen ruber planus given roentgen treatment, 42.5 per cent recovered, 35.4 per cent improved and in 21.9 per cent the results were negative. Of twenty-nine treated with a bismuth preparation 38 per cent recovered, 41.4 per cent were improved and 20.7 per cent were unchanged. Of seventeen treated with arsphenamine, 29.4 per cent recovered, 41.2 per cent were improved and 29.4 per cent were unchanged. Bismuth is cheaper than arsphenamine, more convenient and, properly given, is safe. Especially for patients

who do not bear treatment with arsenic and for whom roentgen therapy is not available, attempted treatment with bismuth compounds is advocated. Improvement sometimes appears slowly. Some cases prove resistant. On the whole, recent cases seem more amenable to roentgen and bismuth treatment than older cases.

\*Pointing Test: Test of Some Hypotheses for Its Clinical Applicability. W. Behrman.—p. 67.

Continued Investigations on Occurrence of Vitamin D in Baltic Herring. G. Blix and Gösta Englund.—p. 203.

**Hyperparathyroidism with Multiple Thrombi.**—In Mellgren's patient, a woman aged 41, previously well, there was sudden onset of continued vomiting and exhaustion, slight infection of the upper respiratory tract, fever and increased sedimentation, with signs of slight kidney disturbance and marked and increasing leukocytosis. Pain in the back appeared and death occurred after two weeks, with a picture of paralysis of the heart. Necropsy showed an enlarged parathyroid gland and calcium deposits in the heart and kidneys, together with multiple recent thrombi in the kidneys and lungs. From experimental results cited the author concludes that the parathyroid extract increases the coagulation ability of the blood as well as its calcium content, and the thrombi in this case are thought to be related to the parathyroidism.

**Influence of Dinitrophenol 1-2-4 on Tar Cancer.**—Vannfält's results afford no evidence that dinitrophenol 1-2-4 in the dosage of 10 mg. per kilogram of body weight daily or from 10 to 20 mg. every second or third day affects the development of tar cancer in mice.

**Pointing Test.**—Behrman's study of spontaneous pointing in normal persons supports the view that the results depend largely on the method applied. Of eleven methods tested, only three are characterized as new. He finds that, in the methods in which the arms approach their aim during an upward movement, the arms deviate outward from the median line; these methods give more marked results after irritation and the effect is increased when no correction is made after each pointing and is further heightened by simultaneous pointing with both arms. In method 10, belonging to this class, in his opinion the best method, there is an average deviation of  $3.79 \pm 0.08$  (0.25) cm. for the right arm and  $3.33 \pm 0.08$  (0.25) cm. for the left arm. The deviation from the variation field of spontaneous pointing increases after calorization, reaching the maximum at about the tenth pointing. Irrigation of one ear with cold water affects the arm of the opposite side, irrigation with warm water the arm of the corresponding side. The caloric test with 100 cc. of warm water causes a stronger reaction than the test with 5 cc. of warm water; the test with cold water results in a more marked reaction than that with warm water, although the difference with regard to the body temperature is the same in the two cases. The deviation in the first pointing to a certain extent determines the deviations in succeeding tests. A table is given for use in determining whether the patient points spontaneously inside or outside the limits of the variation width in normal persons, and for determining whether or not a given vestibular irritation affects the pointing arm. The author asserts that by application of his method about two thirds of the cases react at least in one arm after irrigation of an ear, and two thirds of the persons in whom one irrigation causes no reaction in an arm react when the other ear is irrigated once. After rotation with ten revolutions within ten seconds there is a 93 per cent probability of obtaining some irritation reaction. The diagnostic effect of pointing can be increased by repeated irritation tests. No certain relation between dizziness and pastpointing was established.

## THE GYNECOLOGIC ASPECT OF HUMAN STERILITY

SAMUEL R. MEAKER, M.D.  
BOSTON

The work of Max Huhner on postcoital examination marked the beginning of that interest in the problem of human infertility which has continued without interruption during the past twenty-three years. From the earliest recorded times the childless marriage has been a major problem both for the individual and for society; but only since the beginning of the present century has genuine progress been made toward the correction of this maladjustment.

All recent advances in the diagnosis and treatment of sterility are based on a better understanding of its etiology. These new ideas may be reduced to three fundamental principles.

First, in the great majority of cases of human infertility the cause of that defect is not some single abnormality but rather the summation or totality of several factors. Complete diagnostic studies show that the average childless couple presents 4.79 factors, each of which diminishes to some extent their capacity for conception. It is, of course, always possible that a single abnormal condition may render sterile an individual and consequently any mating into which that individual may enter: this would be true of a blockade in the genital passages, for example, or of any complete impediment to the production of normal gametes. But such factors of absolute sterility, as it may be called, are found in only about 30 per cent of clinical cases. Seventy per cent of couples who apply for the relief of childlessness show no single condition that would account for their difficulty. They do show, without exception, a group of causative factors of which each one lowers their fertility to some extent and of which the sum total depresses that fertility below the threshold of conception.

Second, the multiple factors just discussed are partly genital and partly constitutional. Stock breeders and veterinarians have long recognized the influence that states of constitutional depression exert on the fertility of animals; likewise laboratory workers have found it

easily possible to depress fertility by inducing various types of general debility. But only in recent years have physicians taken account of this important fact. In my opinion, the general or constitutional condition is fully as important as the local or genital condition, with relation to the fertility of an individual. It is worth while to cite briefly the evidence on which this opinion is based. To begin with, one cannot neglect the practical experience of the poultry yard and of the stock farm. Again, constitutional depressions in human beings are accompanied by certain objective evidences, such as a lowered metabolic rate, which naturally indicate a faulty grade of endocrine performance. Also, males of the sort under discussion almost invariably show poor spermatogenesis when the semen is mathematically evaluated; and, as supplementary evidence, their semen usually improves when the constitutional fault is corrected. Finally, the total number of cases in which the elimination of a constitutional depression has resulted in the clinical relief of sterility is now sufficiently large to rule out any likelihood of pure coincidence. I should perhaps add that, according to the ideas of my associates, states of constitutional depression include not only endocrine insufficiencies but also various nonendocrine conditions such as chronic intoxication, metabolic disturbances of extrinsic origin, debility and general inferiority.

Third, the several factors present in each case are seldom limited to one partner. My associates and I find that, among the couples who consult us, only about 10 per cent of the husbands and 5 per cent of the wives are free from all objectively demonstrable evidence of infertility. This statement becomes less surprising on reflection than it might at first seem; for the sterility of a mating is commonly determined by a number of factors sufficiently large so that, on mere probability, one would anticipate some division of them between the two partners. Even when an absolute cause is present, there are still in the background other factors, which become operative when the more obvious impediment is removed. I have long ceased to speak of sterility in men or in women; a more accurate concept, in my opinion, is that of the sterile mating, a union between two relatively infertile individuals.

The foregoing remarks on the causation of human sterility make clear the complex nature of the problem and the need for an elaborate diagnostic approach. It goes without saying that the urologist and the gynecologist must make detailed studies of the genital organs; no less important are the services of the internist and the endocrinologist. Complete investigation of every case is necessary in order to obtain the best results; for there could be no worse fallacy than to accept the first discovered abnormality as the sole

From the Evans Memorial of the Massachusetts Memorial Hospitals, and the Department of Gynecology of the Boston University School of Medicine.

Read before the Section on Urology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

The conclusions reported in this paper are based on an organized group study of sterility, in which I have had the collaboration of Dr. Harold Bowditch, Dr. Charles H. Lawrence, the late Dr. Allan Winter Rowe, and Dr. Samuel N. Vose. Data other than gynecologic are contributed by my associates. The laboratory-endocrinologic work has been done at the Evans Memorial for Clinical Research and Preventive Medicine, a department of the Massachusetts Memorial Hospitals.

and only cause in the case under consideration, on an unjustifiable assumption that no other causative factor is present. In the past, unfortunately, this illogical procedure has been the rule.

I appreciate this opportunity of conferring with the Section on Urology, and I wish to express my admiration of those contributions which it has made in the domain of this discussion. The relative unimportance of male genital abnormalities has been shown and, notably, a technic for the accurate evaluation of semen, a study of which the results represent with admirable precision the several grades of male fertility, has been developed.

Those aspects of the problem which fall within my own field can be briefly summarized. Rareties being excluded, there are four important groups of gynecologic factors of infertility:

The first of these is female genital hypoplasia. Whether such a defect is an end result of overcivilization, I do not know; but the fact remains that today numbers of women possess genital organs scarcely developed beyond that stage of differentiation which would be normal in a 10-year old girl. Hypoplasia is inimical to fertility in several respects, chiefly as regards immaturity of the ovaries, which ovulate imperfectly if at all.

Second, the endocervical mucus is often so thick and tenacious that spermatozoa are unable to penetrate it. Faults of this sort are demonstrated by postcoital examination, a test which should always be performed though it never eliminates the need for study of a condom specimen. Abnormal viscosity of the endocervical secretions may derive from several causes, among which the commonest are poor drainage, due to a pinhole os externum, and endocervical infection. Faulty sex hygiene, with resultant chronic passive congestion, is a factor never to be overlooked.

Third, partial or complete obstruction of the fallopian tubes constitutes an obvious impediment to conception. No doubt gonorrhea plays the major rôle in producing this particularly unfortunate factor. Nevertheless other causes are to be considered: developmental defects, for example, and nonvenereal inflammations.

Fourth, and last, there is the serious matter of deficient oogenesis. Here one gets into exceedingly deep waters. For not only must the ovary be mechanically free to liberate mature egg cells, but the gland must also be able to create that divine spark, that sum total of hormones, which will endow the ovum with adequate vitality. And, on both counts, failures are numerous. Many an ovary is inhibited on purely mechanical grounds, when retention cysts or a thick tunica albuginea interferes with the normal maturation and rupture of follicles. It may also happen that graafian follicles never tend to mature; in such cases the cause is to be sought in some generally depressed state, most often in an absence of that stimulation which should normally come to the ovary from the anterior lobe of the pituitary.

The gynecologic investigation of a sterile mating involves a long series of routine procedures: history and abdominopelvic examination, with particular reference to certain details that are not of great importance in ordinary gynecologic cases: measurement of the uterine index, tests of tubal patency, study of the endocervical secretions, and postcoital examination. Most of these tests are generally familiar, and it is unnecessary to discuss them in detail. There remain two diagnostic items which deserve a special word of comment.

Since the factor of hypoplasia is exceedingly important in every case of deficient oogenesis, the gynecologist naturally desires to evaluate defects of this sort with the utmost accuracy. For the purpose of quantitative estimation, my clinic has used for ten years a measurement which we call the uterine index. This is an expression of the ratio between the length of the uterine body and the length of the cervix; the relation is 0.25 in infantile cases and 0.75 or more in cases in which normal development has been attained. Figures thus obtained are far more significant than a casual notation of such stigmas as an elongated and anteverted cervix.

The most obscure detail in every case of sterility is the question of effective ovulation. No method of examination has ever been sufficient to determine whether or not the ovaries actually liberate mature and normal eggs. Menstruation obviously proves nothing in this respect; some women flow regularly without complete follicular activity in their ovaries, while others conceive even during times of amenorrhea. A great deal of interesting work has recently appeared on the problem of so-called anovular bleeding; that is to say, of a uterine flow not dependent on the rupture of a graafian follicle with consequent formation of a normal corpus luteum. I believe that in all such discussions there is a certain tendency to separate arbitrarily, and perhaps wrongly, the idea of mature and complete follicular activity, and the concept of a follicular cycle which, even though abortive, may still produce a certain number of lutein cells. That is why I do not accept without some question the conclusions based on endometrial biopsies, however well they appear to indicate successive events in the physiologic program of the ovary.

The way of treatment is clearly indicated by a complete diagnostic study. In general, one should aim to correct all the factors demonstrated as inimical to fertility. A multiple therapeutic approach gives results far better than those obtained in older days, when treatment was limited to one or two items. It does not follow, however, that complete treatment should be undertaken from the start, since good judgment often dictates the wisdom of eliminating certain factors before others are attacked. Notably, it is essential to assure an adequate grade of male fertility before subjecting a wife to any therapeutic measures directed primarily against sterility.

In the gynecologic field, methods of treatment are fairly well standardized. Endocervical infections may be cured with the cautery, and, if a pinhole os prevents free drainage of the secretions, a small posterior median discission can be done. Insufflation of gas and injection of iodized oil relieve many partial tubal obstructions; in fimbriated-end occlusions salpingostomy is a valuable procedure, provided this is invariably accompanied by postoperative measures that will maintain the established patency. Deficient oogenesis calls for the services of the endocrinologist or of the internist more often than for those of the gynecologist; nevertheless I am of the opinion that conservative operations on the ovaries, notably the resection of retention cysts, are of great utility for the purpose of restoring normal follicular function. The factor of hypoplasia remains exceedingly difficult to manage in the adult patient, in whom all developmental urge or growth impulse has been lost. But there exists in this connection a brilliant opportunity to practice preventive gynecology, for it appears that most of such developmental arrests can

be foreseen and forestalled by proper attention to the menstrual behavior and to the general health of the adolescent girl. I would say that the entire project of preventing human infertility is more important and more hopeful than everything that can be accomplished at present in the way of curing established cases.

475 Commonwealth Avenue.

## METHODS IN SPERM ANALYSES AND EVALUATION OF THERAPEUTIC PROCEDURES

ROBERT S. HOTCHKISS, M.D.

NEW YORK

The problem of human infertility has opened a new realm for thought and ingenuity, for it entails the unique implication of a pure creative endeavor within the practice of medicine. The proverbial mission of the physician has long been that of alleviating pain, combating and controlling disease and observing and assisting the physiologic processes of the body in health and in illness. The ultimate objective of the correction of disturbed fertility is the production of a new individual from a source that has hitherto been barren. Such a commendable motive deserves from the profession the serious deliberation it requires.

From Biblical times until the present century the wife has borne the burden of blame for failure to produce offspring, for until twenty years ago no serious studies of male fertility had been undertaken. It is now generally agreed that the husband bears the chief or partial responsibility in approximately one fourth of the involuntary barren marriages and accordingly his examination is now regarded to be as important as that of his wife.

This past indifference to the male was undoubtedly due to numerous influences and misconceptions. The erroneous belief that potency was ample evidence of fertility has happily been dispelled. Fear of offending the masculine ego by questioning his fertility is no longer a formidable hazard, yet certain men are still apprehensive that a previous venereal disease might be disclosed as a result of such an examination. It is likely, however, that the real explanation for the negligence toward the male was due to the lack of time and inclination on the part of the physician to consummate a complete investigation.

The purpose of any study of infertility is not only to detect absolute sterility but rather to arrive at an estimation of the relative fertility of each partner, each to be considered separately and together as a marital unit. The power of reproduction depends on the sum total of the details of the germ plasm, the physical status of the subjects and their ability to have coitus. If the combination of these factors is below "the threshold level for fertility," no issue will result from the marriage even though each constituent may possess varying positive degrees of fecundity. There is therefore a difference in the grade of fertility of each marriage as well as of the individual. This is demonstrated in instances in which one person proves fruitful to one mate yet barren to another. It accordingly becomes the goal of the physician to detect and possibly

overcome the causes of absolute sterility or to enhance the existing fertility to a level at which conception may occur. The latter may involve the correction of a number of faults in one or, more usually, in both partners.

The appraisal of the semen constitutes the chief and final index of male fertility, and one must be able to recognize relative degrees of seminal deficiency and learn to correlate these with the clinical data to determine whether the husband is the chief or contributing factor to the barren marriage. It is difficult to construct an intelligent opinion if the examiner is deprived of an examination of the male patient or is without a report of the status of the female. Such is the case, however, if the semen alone is delivered for analysis.

If it is borne in mind that spermatozoa are able to exhibit motility longer in low temperatures than at body heat and that the ingredients of the average condom are hostile to their life, much error and confusion will be avoided by proper instructions relative to the method of collecting the semen for analysis.

Following a period of three days' abstinence, the ejaculation is collected directly into a wide-mouth glass container and allowed to remain at room temperature or lower until delivered, within one or two hours, to the examiner. An active specimen will exhibit motility for thirty hours or longer under these conditions.

The spermatozoa in the semen may be compared to the populace of a large city, for in each there are young and immature individuals, aggressive and sluggish types, malformed members, and the old and dead. It is probable that the spermatozoa derive the nutrition for their activity from the abundance of dextrose that is found in the fresh specimen in from three to six times that present in an equal amount of blood.

A routine semen analysis should include the following details:

1. The average volume of the ejaculate is from 3 to 4 cc. Variations from one or two drops to 10 cc. are encountered. Specimens of less than 0.5 cc. in amount fail to produce an adequate seminal pool, which ordinarily provides a medium for the survival and protection of the sensitive sperm.

2. The appearance and viscosity of the fresh ejaculate is entirely different from that one-half hour old. Self liquefaction is then completed, much to the benefit of motility of the sperm. If the eventual motility is of a good grade it is likely that variations in viscosity have little or no clinical significance.

3. The  $p_H$  of a seminal specimen usually falls within the range of from 7.7 to 8.5. If no motility is found it is of particular importance to obtain a  $p_H$  determination, for in rare instances a shift to a low reading of 6.0 and 6.2 has been found to be associated with necro-spermia.

4. It is extremely difficult to give a word picture of the description of the motility of the spermatozoa. The type of activity, the number crossing a microscopic field and the percentage of inactive cells are all details of interest. Interval examinations are made to determine the viability of the sperm, which is usually about twenty-four hours at room temperature.

5. The number of spermatozoa is determined by the use of the usual equipment for counting blood cells. A sodium bicarbonate-phenol solution is used as the diluent; it destroys motility to permit an accurate estimation of the cells present in each cubic centimeter and in the total ejaculate. The average fertile male will produce from 100,000,000 to 150,000,000 sperma-

From the Department of Surgery (Urology), New York Hospital, Cornell University Medical College.  
Read before the Section on Urology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

tozoa per cubic centimeter or from 400,000,000 to 500,000,000 in the total ejaculate. One group of eminent authorities state that in their experience pregnancy does not occur if the cell count is below 60,000,000 per cubic centimeter. I have on record a few exceptions to this rule and believe the more reliable and consistent cell counts have been on the basis of cells present in the total volume of the ejaculate rather than in units of cubic centimeters. The bulk of the semen undoubtedly originates in the prostate and seminal vesicles, and variations in the amounts of these secretions will accordingly dilute or concentrate the specimen. In the former instances an apparent deficiency may be inferred if the cell count is expressed in cubic centimeters, whereas the number of sperm in the total ejaculate may prove to be normal. Here, as elsewhere, dogmatic rules are dangerous, and it is unlikely that any figure can be decided on as a fixed minimum. When fewer sperm are found, the chance of fertilization is mathematically and proportionately reduced until a theoretical point is reached at which impregnation is most unlikely. A simile may be found by comparison with the laws of chance as it affects a hunter shooting at a difficult target with a shotgun: his chances of hitting the object are enormously reduced if the shell is loaded with ten shot rather than with 125 of the same size and weight.

6. The examiner must be familiar with the variations in the morphology of the spermatozoa just as the hematologist is conversant with blood cytology. A stained smear is prepared and the percentage of atypical cells is established by count. If some of the more complicated stains are not available, the Gram stain gives a fair visualization of the cell structure after proper fixation. Moench<sup>1</sup> has evidence that leads him to believe that, if more than 20 per cent of the cells have abnormal form, sterility or miscarriage will result. In an incomplete but rather large group of cases of proved fertility now under study I have yet to find an instance of a normal pregnancy attributable to a seminal specimen with excessively large numbers of abnormal sperm, yet this condition is not infrequently encountered in cases of disturbed fertility. Veterinarians are familiar with this breeding defect in male animals and have means of offering proof of male faults that cannot be obtained in human studies.

The test of time leaves the future to determine the actual value of this important theory, as information is compiled to substantiate or refute the current principles of sperm morphology.

The following cases are herewith presented to illustrate principles in the method of diagnosis and management of certain defective husbands. All examinations, treatments and inseminations of the females were done by gynecologists in private practice or in the gynecology department of this hospital. Abstracts of the records of both husband and wife are included for the sake of completeness and clarity.

#### REPORT OF CASES

CASE 1.—*Husband*.—The chief complaint was that there was no ejaculate, and the marriage was barren.

For the duration of his two and one-half years of married life the patient had never produced an ejaculate, although he obtained erections and had coitus once or twice each week.

1. Moench, G. L.: Sperm Morphology and Biometrics, *M. Times & Long Island M. J.* 62: 33-35 (Feb.) 1934; Sperm Morphology and Microdissection, *Am. J. Obst. & Gynec.* 18: 53-56 (July) 1929; Sperm Morphology and Biometrics, *Am. J. Obst. & Gynec.* 25: 410-413 (March) 1933; Evaluation of Motility, *J. A. M. A.* 94: 478-480 (Feb. 15) 1930; Technique of Study of Cytology, *Am. J. Obst. & Gynec.* 19: 530-538 (April) 1930. Moench, G. L., and Holt, N.: Number of Spermatozoa and Fertility, *Urol. & Cutan. Rev.* 33: 814 (Dec.) 1929; Sperm Morphology, *Am. J. Obst. & Gynec.* 22: 199-210 (Aug.) 1931.

He appeared eight years younger than his actual age of 25 years. There was no beard, and the body hair was absent except for the pubic region, where it had a typical feminine distribution. The external genitalia were of the size and development of a 10 year old boy and the prostate was palpated with difficulty. Massage failed to produce any secretion from the gland.

Roentgenograms of the skull and routine laboratory tests were negative except for the sugar tolerance tests, which demonstrated a small elevation and rapid fall to the blood fasting level. Repeated efforts to produce a small amount of semen were without success.

*Wife*.—The wife was essentially normal (gynecologic report).

*Treatment*.—The husband received 200 units of the gonadotropic factor from pregnancy urine, daily for five weeks. At the end of that time his ejaculate consisted of one drop of semen containing from six to eight normal spermatozoa per high power field. For the subsequent thirteen weeks gonadotropic substance (200 units) intramuscularly was alternated daily with 20 units of solution of anterior pituitary. At the end of eighteen weeks about two drops of semen could be produced, containing from 100 to 200 spermatozoa per high power field, and a definite increase in the libido was reported. This type of therapy was continued with the addition of weekly prostatic massage and in eight months from the beginning of the treatment the ejaculate measured 0.2 cc. and possessed numerous highly motile spermatozoa. At the end of fourteen months the following semen analysis was made: volume 0.75 cc., viscosity and turbidity above normal, motility excellent, vitality twenty hours; count per cubic centimeter 76,000,000, total for ejaculate 57,000,000.

*Morphology*: A stained specimen revealed normal cell formation.

*Result*.—The wife became pregnant seventeen months after the inception of therapy and was delivered of a normal female child.

In my experience this favorable result has been decidedly unusual. In a number of similar cases the same treatment was administered without results. It would appear, however, that long periods of endocrine therapy may be necessary if results are to be anticipated. Predictions are hazardous and the actual mechanism of the gonadotropic action of these products still remains purely theoretical. No change in the patient's appearance or body structure was apparent at the end of the treatment.

CASE 2.—*Husband*.—The husband, aged 35, was apparently healthy and well developed. His sexual ability and habits had been normal during the five years of married life, yet there had been no signs of pregnancy.

The entire physical examination failed to disclose anything of importance except a boggy prostate gland containing a few pus cells.

The laboratory data were essentially negative but the semen analysis disclosed the following: volume 1.75 cc., *fu* 8.0; motility: one hour poor grade (from 10 to 15 cells motile per high power field), eight hours sluggish, ten hours very slight motility; cell count per cubic centimeter 18,000,000, total for ejaculate 31,200,000 (low); morphology: large numbers of spermatozoa and immature forms; 28 per cent of adult cells were of abnormal morphology. A diagnosis of a defective seminal specimen was made on the basis of poor motility, low count and abnormal cell structure.

*Wife*.—A thorough examination by a gynecologist revealed nothing abnormal except for a slightly hypoplastic cervix not sufficient to explain the infertility.

*Treatment and Course*.—The husband was treated as in the previous case, with the inclusion of thyroid substance by mouth and a high vitamin diet. At the end of twelve months he had gained 12 pounds (5.4 Kg.), yet no material change in the semen was noted except for increased motility and vitality.

At the end of fifteen months the estrus period was studied by the vaginal smear method (Papanicolaou-Shorr) and five artificial inseminations were attempted with the husband's semen at various times in the probable ovulatory phase during

the ensuing five months. No results followed. At the request of both husband and wife, foreign semen (an excellent specimen) was used for the insemination. Pregnancy occurred after the third attempt. A normal birth duly followed.

This case is presented to illustrate the necessity of a detailed semen analysis to detect male deficiency. Although numerous spermatozoa were produced, the husband was "sterile" to his wife. Artificial inseminations with defective specimens do not correct the cause of the barrenness and are most apt to be useless. Therapeutic measures failed in this instance to alter the character of the semen.

**CASE 3.—Husband.**—The husband, aged 35, was deformed and somewhat obese, with an arthrodesis of the right hip due to tuberculous of the joint in childhood. For the nine years of married life there had been no signs of pregnancy. The semen had been analyzed on several occasions and reported to be satisfactory, but no physical examinations had been done for the problem of infertility.

On examination the meatus was found located proximal to the glans, opening on the ventral surface of the shaft of the penis. A diagnosis of hypospadias was made. The other examinations revealed no unusual disorders and the semen was found to be satisfactory, as evidenced by the accompanying report: volume 3.75 cc., appearance and viscosity normal,  $pH$  8.1; motility: two hours excellent, six hours very good, twelve hours good, twenty-four hours slight; morphology, 93 per cent normal oval type; count per cubic centimeter 128,000,000, total for specimen 416,000,000.

**Wife.**—Gynecologic examination disclosed a myoma of the uterus. This was removed and six weeks thereafter the pelvic organs were normal to palpation and roentgenologic examination.

**Course.**—No pregnancy occurred during the following seven months from the date of full recovery from the operation. The ovulation period was studied by the vaginal smear method (Papanicolaou-Shorr), and artificial inseminations were done with the husband's semen. Pregnancy occurred after the third month of these procedures.

The husband believed that he was totally without fault by virtue of the favorable semen analysis performed two years before this study was begun. It is possible and probable that the hypospadias interfered with the proper deposition of semen. This case of "marital sterility" is presented to demonstrate in particular a combination of faults in the two partners and to emphasize the importance of complete investigation of both husband and wife.

**CASE 4.—Husband.**—The husband had contracted gonorrhea fifteen years before and suffered from a bilateral epididymitis. All traces of this infection had disappeared but his seven years of married life had been without offspring. At the age of 37 he was in the best of health and, with the exception of slight induration of both epididymides, was found to be normal.

Repeated examinations of his ejaculate showed the complete absence of spermatozoa, and a diagnosis of bilateral blockage of the epididymides was made.

**Wife.**—The wife was found to be entirely without fault and no cause for the infertility could be assigned to her.

**Treatment.**—A bilateral vaso-epididymal anastomosis was done and many spermatozoa were recovered from aspiration of the globus major of each epididymis.

During the six weeks postoperative period the ejaculate contained a few sluggish spermatozoa, but these disappeared when subsequent specimens were observed until they were again present in the specimen at the end of five months. At that time the following specimen was obtained: volume 4.5 cc.,  $pH$  8.0, viscosity normal; motility: one hour excellent, six hours very good, twelve hours good, twenty-four hours, from 10 to 15 cells motile per high power field; count per cubic centimeter 101,000,000, total for ejaculate 452,000,000; morphology: a stained slide demonstrated normal cell structures.

**Course.**—The wife became pregnant eight and one-half months after the date of operation.

This presents again the fact that occlusion of the vas does not destroy the spermatogenesis of the affected testicle. The results of such an operation may not be apparent for several months and repeated studies of the semen are advisable even if spermatozoa may not appear for a long period after the anastomosis has been attempted.

#### SUMMARY

A competent investigation of marital infertility must include a careful examination of both partners. The relative fertility of both husband and wife must be established to determine the grade of fertility of the marriage. Wide variations exist in the fertility of men as determined by semen analyses.

The semen constitutes the chief index of male fertility. The proper evaluation of its fertilizing power is dependent on the complete analysis of the various factors and constituents of the specimen.

Male defects may be eradicated or improved in certain instances. Caution is advisable in anticipating or predicting results from the administration of endocrine products. These may be striking in some instances and yet entirely lacking in other apparently similar cases.<sup>2</sup>

## THE OPERATIVE TREATMENT OF STERILITY IN THE MALE

FRANCIS R. HAGNER, M.D.

Professor of Genito-Urinary Surgery, George Washington University  
WASHINGTON, D. C.

The most frequent cause of sterility in the male is inflammatory occlusion of the epididymis or vas deferens. It is solely to this cause and its treatment that I shall limit my discussion in the present paper.

Atrophy of the testicle very rarely occurs in epididymitis, especially in the type associated with gonorrhea. I say this from my experience in the operative treatment of gonorrheal epididymitis, as in more than 300 cases I have never found evidence of involvement of the testicle itself, the epididymis and tunica vaginalis seeming to bear the brunt of this infection.

Traumatic epididymitis rarely leads to sterility. I have recently had a patient who had an injury ten years ago, apparently not very severe, to both testes. He was examined by a doctor in another city. In the examination, eight months before I saw the patient, a needle was inserted into the epididymis, and it is said that live spermatozoa were obtained. At the operation the globus major on each side was found to be very dark and on incision appeared as an organized blood clot. On one side there was a very small abscess, but no spermatozoa were found, although the vas was patent. It was useless to make an anastomosis, and therefore none was made.

From my experience in this case I should rather deprecate the exploring of the epididymis with a needle. In none of my successful cases was this done.

In bilateral gonorrheal epididymitis the healing process leads to the formation of scar tissue, which causes an occlusion of the efferent ducts of the epididymis,

2. Special acknowledgment is made to Dr. Ephraim Shorr, Department of Medicine, New York Hospital, for his kindness in the care and management of those patients, whom he examined and treated in his department of endocrinology.

Read before the Section on Urology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

and this prevents the egress of the normal spermatozoa, which are formed by the unaffected testes. The globus minor is the portion of the epididymis most involved. It is in this very portion that occlusion has the most dangerous results, as there is here but one efferent duct,

while in the globus major the efferent ducts are numerous and the obstruction of one or two would still leave open other channels.

It was because of the known patulence of the globus major following gonorrheal epididymitis, when the globus minor and the vas deferens in this region became occluded, that the anastomosis of the

vas deferens and the globus major was made by Dr. Edward Martin of Philadelphia, who was a pioneer in this field. The endeavor to overcome the occlusion by such an operation offers the only chance of recovery.

I have never had a successful case following operation for sterility in which the patient has not had a history of bilateral epididymitis. There are two conditions that must be present for a successful result in sterility of this type: first, the vas must be patulous

some cases in which occlusion was present. The globus major in a favorable case is, as a rule, easily palpable and has a rather full feeling on palpation. If the globus major is not palpable it may be entirely obliterated by fibrous tissue, with the ducts occluded and no spermatozoa discoverable.

As stated in previous papers, I have had no successful cases except those in which silver wire was used as a suture. I had one case in which I used very fine silk at the first operation, but it resulted in a failure. This patient was subsequently reoperated on, and the silver wire was used, with a cure resulting. I cannot explain this circumstance, but it is my impression that there is less tissue reaction from silver wire than from any other type of suture. I feel that I have proved this conclusion by experimentation on animals.

In some of my patients on whom I have reoperated after an initial failure, the silver wire sutures had the

Fig. 1.—The beading of the cord which is often present when the lumen is occluded. On incision a thick yellow material escapes.

Fig. 2.—The vas opened and silkworm gut passed up the lumen. Incision into the globus major and the tubules cut across.

above the point of the anastomosis; second, the globus major, or the upper portion of the body of the epididymis, must contain live spermatozoa. If these conditions are not present it is futile to expect a cure from the operation.

I have been able by careful palpation of the vas, on noting a beaded condition, to make a prognosis of occlusion preoperatively in a number of cases. I have at times failed to make this preoperative diagnosis in

Fig. 3.—The placing of the fine silver wire sutures to complete the anastomosis.

same appearance as at the time they were inserted, twelve or more months before, with very slight formation of fibrous tissue.

I shall only briefly mention the steps of the operation, as these have been reported so many times that I think repetition is unnecessary. It is an interesting fact that I have not had a single case of impotence in any of the patients who were sterile.

I have had four atypical cases, three in which the vas was occluded on the side in which the epididymis had live spermatozoa, whereas on the opposite side no spermatozoa were found though the vas was patulous. A crossed anastomosis was done; that is, the patulous vas was brought through the septum of the scrotum and anastomosed to the epididymis that contained the live spermatozoa. Unfortunately these cases failed of cure. The fourth was more successful. A doctor from North Carolina presented himself, and at the time of operation I found an occluded vas on the left side and a scarred globus major with no spermatozoa. On the right side the globus major was replaced by a moderate-

sized spermatocele that contained actively motile spermatozoa. An anastomosis was made between the vas and the spermatocele. In six weeks this patient had actively motile spermatozoa, and his wife became pregnant within two months and was subsequently delivered of a normal child.

Every urologist knows that, when operating on a spermatocele, he is liable to a recurrence unless he removes every part of the sac (which means the removal of the small duct that leads into the cyst). I assume that the same condition obtains in individuals in whom a cure is procured; namely, that a sinus is formed between the incised vas and one or more tubules in the epididymis that act in the same way as the duct that leads to a spermatocele.

A failure at one time, if live spermatozoa are present and if the vas is patulous, is not a contraindication to a second operation. In some of my most successful results I have had a failure the first time, with a favor-

not to make the incision in the vas too high up, thus giving a double chance for a cure and, in case of failure the first time, allowing for a subsequent operation.

Fig. 4.—The anastomosis completed. The silver wire sutures are drawn up and twisted.

able outcome at the second operation. The time of the appearance of the spermatozoa varies. I have had individuals who have produced actively motile spermatozoa one month after operation and others varying from one month to nearly a year. I do not reoperate under one year, as I have had successes that did not manifest themselves until eight or ten months after operation. In one case the first evidence of a cure that the patient noted was his wife's pregnancy. He was in an unhappy frame of mind until we found that he had thousands of spermatozoa.

Before operation, repeated examinations for spermatozoa have been made either by myself or by the surgeon referring the patient. Some patients have been sent to me as sterile who were found not to be so. It is most important to examine an ejaculated specimen of semen and not rely on that obtained by massage of the prostate and seminal vesicles.

It is important to control all bleeding either by torsion or by pressure before the anastomosis is made. I have always done a bilateral operation, being careful

Fig. 5.—First step in anastomosing the vas deferens with a spermatocele.

In the sixty-five cases here reported there were seventy-seven operations. Twelve patients were reoperated on because of initial failure. Of these twelve, seven were cured by the second operation.

Fig. 6.—Completed operation.

Nearly all my operations have been done by lateral anastomosis except the few rather atypical ones already mentioned. Sometimes one finds occlusion of the vas at the first incision, and by going farther up the vas one is able to get above this obstruction. Unless great

care is exercised to cut only into the lumen of the vas, which is recognizable by the yellowish tinge of its lining, there is likelihood of the operator carrying the incision through the entire diameter of the tube. It is important not to strip the vas deferens too close. I place the first suture at the distal end of the incision in the vas, taking a good heavy bite, as this is the anchoring suture for the operation and the obstruction is below this point. The suture is then anchored firmly in the lower end of the elliptic incision of the epididymis. Two lateral sutures are then placed to take a fairly heavy bite in the epididymis and include some of the cut tubules. If only the fibrous covering of the

in order to avoid the formation of scar tissue no local infiltration should be used. The operation cannot compromise the function of an organ that has already proved functionless. In no class of cures will the surgeon be rewarded by his patients with a greater warmth of gratitude.

1835 Eye Street, N.W.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MEAKER, HOTCHKISS AND HAGNER

DR. VICTOR D. LESPINASSE, Chicago: Dr. Meaker pointed out that an examination as to the etiologic diagnosis of sterility includes a complete physical examination: the state of body and the state of mind. With regard to pathologic secretions it is rather curious that pus in prostatovesicular infections sometimes is deadly to the life of the sperm and at times is not. The Huhner test, as Dr. Meaker brought out, is a valuable procedure; it determines the reaction of the spermatozoa to their normal, natural environment. A point of considerable importance in the male is the size of the prostate. If a young man, 25, 30, 35, has a soft, succulent prostate, I feel that he is a pretty good man from a sex standpoint. When semen is first ejaculated it is quite thick, quite viscid if it is a normal specimen. Some specimens never coagulate; they are thin and watery from the start and in my experience are poor specimens. The evaluation of sperm is not permanent; it is not like blood groups. The sperm is a very good index as to the general bodily condition. If one has a good live sperm it is very likely that the bodily condition is excellent. It is surprising what a normal spermatozoon can do. It can travel all around the country and still impregnate. I did some experimental work once wherein I rigged up a doe's reproductive system so that the sperm had to go up the right side, across the abdomen and come down into the left uterus to impregnate, and they did. Granted that there are no sperm in the semen, the condition is due either to obstruction or to lack of production. I regard testicular or epididymal puncture a very poor procedure. In obstructive sterility it is always a question as to where the obstruction is, and one presumes that it is where the palpable infiltration is; but the real obstruction may be in the vas. The infiltration is usually greatest in amount, as Dr. Hagner has mentioned, in the globus minor, but one should feel the vas. In these cases of obstruction the testicular tension is a little higher than normal and there is oftentimes a small hydrocele with adhesions.

DR. LAWRENCE R. WHARTON, Baltimore: A great many women conceive who have a minor obstruction of the fallopian tube that can be overcome by the pressure of gas, by the Rubin test. On the other hand, I think Dr. Meaker will probably agree with me that, if the lumen of the tube has been obliterated and the walls have been sealed by inflammation, the situation is bad. Endocrinology is one of the most difficult problems to measure, because in this domain there is no uniformly accepted standard, no yardstick by which the patient can be measured. Young women may have metabolic disturbances which are temporary and which do not interfere with subsequent normal conception. Of course, very few are completely normal, and there are many women who have slight endocrine disturbances, who are slightly over weight, who have a slightly changed metabolic rate, and they are normally fertile. It is difficult to measure these cases by a standard rule. In the last ten years the progress in this domain has been immense, and in the same measure in which progress has been made, I think further progress will be made by the careful work of men in laboratories, in clinics and in offices. There is one feature of sterility in women which has not received much attention. I refer to phenomena concerning ovulation. Ovulation is just as important as spermatogenesis. We see the sperm cells, we know whether they are healthy, we know whether they are being formed in normal proportions, but we don't see the ova, we don't know whether they are healthy, we don't know whether in some cases they are even being formed or not. This problem has been studied rather actively in the last year. There are certain definite features that accompany ovulation in many women. These women have a slight mucoid discharge at that time; many women have a slight micro-

Fig. 7.—Anastomosis of the vas through the septum of the scrotum to the opposite side.

epididymis is taken up in the suture, the cut tubules drop back when the anastomosis is made. The suture is then passed through the cut edges of the vas, just enough tissue being taken to approximate the edges. The last suture is passed in the same way through the upper end of the incision in the epididymis. It is then

Cures (63.6 per cent.).....	
All presented numerous motile spermatozoa; 16 of the 21 begat one to six children, although one was a miscarriage	

passed through the vas, at the upper angle of the incision, being carefully placed so as not to occlude the lumen. I test this out with a tear duct probe. The anastomosis is then complete. The instruments that I use are iridectomy knives, scissors and artery forceps such as those commonly used in operations on the eye.

The operation, while tedious, is not dangerous to life. I have always used general anesthesia. I have felt that

scopic trace of blood in the cervical secretion, and that can be determined by vaginal washings. Vaginal secretions change. Endometrial biopsies sometimes tell whether or not ovulation is proceeding. Some women even have a little discomfort at the time of ovulation, nausea, at times a little pain between the menstrual periods. One cannot be certain, however, for some women have all these signs and are not ovulating. Two Frenchmen, Simonnet and Seguy, have made a similar observation. This is a domain in sterility which has not been studied as I hope it will be. The problem of sterility has so many ramifications that one cannot touch them all. But the problem of sterility is not being handled as it was a few years ago. It is not the money making proposition, perhaps, that some other forms of surgery are. There is nothing spectacular about it. It takes a lot of hard work and is done usually by those who are deeply interested in it.

DR. MILEY B. WESSON, San Francisco: I want to express my appreciation to Dr. Hagner for this presentation and for his original paper on the subject read in Philadelphia six years ago. Those who learned their surgical technic from the late William S. Halsted of Johns Hopkins Hospital know that silver wire is the suture of choice in all cases in which round cell infiltration about the stitches will vitiate the end results. Most surgeons have apparently forgotten his teachings. Dr. Hagner not only has profited by the precepts of his mentor but has called it to my attention on two occasions. The Hagner operation is a success because of the use of silver wire sutures. I have seen silver wire removed from the sites of herniotomies many years after they have been placed, and they were as bright and shiny as when introduced.

•DR. J. H. TURNER, Houston, Texas: I have seen, in operating for acute bilateral epididymitis, cases in which both epididymides have been completely sectioned and a drain put in, and afterward these patients were fertile. On several occasions in our clinic we have purposely sectioned the epididymis and tied in a silkworm-gut drain for several days, allowing the patent ends of the tubules of the epididymis to unite. The operation for surgical treatment of the epididymis has previously been described by my brother, B. W. Turner. He also described the technic of excision of a nodule of the vas and the anastomosis. In cases in which the obstruction is above the inguinal ring we have been able to establish communication by passing a long silkworm-gut drain through the vas and afterward injecting some physiologic solution of sodium chloride, an insufflation of the vas, so to speak.

DR. SAMUEL R. MEAKER, Boston: My associates and I believe that one year of involuntary sterility justifies the carrying out of a complete diagnostic study. A year or two of delay in young patients would make little difference; but I feel strongly that when a woman is over 30 no time should be lost, because the definite peak of female fertility arrives some time in the midtwenties. From 30 on there is a steady diminution, so that delay in investigating these patients when the wife is on the down grade of fertility inevitably lessens the chance of successful results. I am glad that Dr. Lespinasse emphasized the item of diet, which I mentioned briefly. The ordinary mixed human diet contains all the vitamins needed, and more, including vitamin E. The fact that one can render laboratory animals infertile by putting them on artificial mixtures of foods lacking in various elements proves remarkably little with regard to human beings. In general one should be cautious about transferring conclusions based on the fertility of laboratory animals, maintained as they are under artificial conditions, to clinical human cases. My associates and I believe that the most important factor in the diet is protein insufficiency or protein starvation. In many of our patients, particularly male patients, in whom the semen gives a quantitative measure, whose protein intake is inadequate, the correction of that fault has brought about an objectively demonstrable improvement and not rarely a cure of sterility. Another point mentioned by Dr. Lespinasse is well taken; namely, that the seminal production, far from being constant, varies from time to time. I have repeatedly noticed great variations in the quality of seminal specimens, either for better or for worse, over a short period of months. These can usually be correlated with the constitutional state of the individual. I agree with Dr. Wharton that we are far indeed from having arrived at the desirable degree of technical

perfection in dealing with tubal occlusions. In fact, we are so far from it that I myself am extremely disinclined to operate on any type of tubal blockade other than simple occlusions at the fimbriated ends.

DR. FRANCIS R. HAGNER, Washington, D. C.: Some of these semen donors write, speaking highly of themselves and their personal appearance. One thing that I failed to mention is that when the tubules of the epididymis are cut across to obtain the specimen to note the presence of motile spermatozoa, sometimes when it is put on a warm slide the spermatozoa are not motile. If a little warm physiologic solution of sodium chloride is run on the slide, active motility will be noted. Dr. Lespinasse spoke of the absence of the vas deferens. I had a case last year in which there was complete absence. I presented my case before the Congress of Surgeons and was going to do a vaso-epididymostomy. When I got in there I could not find the vas. I have also felt that leaving a drain would rather tend to the formation of scar tissue, and I have never done that because I think that in these operations it is desirable to obviate the presence of scar tissue as much as possible. An attempt is made to stop hemorrhage by pressure with small artery forceps. I would like to say a word about the epididymotomy operation. When I reported these cases many years ago I distinctly impressed the importance of not cutting the epididymis but to do multiple punctures and then pass a probe in and work it back and forth to evacuate the pus. I believe that in a good many of those cases if a wide incision is made there is much more liability to have sterility following such a procedure. Dr. Cunningham and I have had about the same relative number of cases in which a bilateral epididymotomy was done, and the incidence of sterility in those cases is about 40 per cent, which is about the same as in those in which operation is not performed.

## ENDOCRINE FACTORS IN STERILITY

RICHARD CHUTE, M.D.

BOSTON

Among the causes of deep unhappiness in marriage, sterility ranks high and has always done so from the beginning of history. A home without children lacks the stability of a home organized on a normal biologic and family basis with children. In a childless marriage, husband and wife are not held together by that strong common bond which leads parents to subordinate their own selfish desires gladly for the common welfare of their family.

The prevalence of sterility and thus its magnitude as a problem is indicated by the fact that, according to recognized authorities,<sup>1</sup> somewhat more than 10 per cent of all marriages in the United States and England are sterile, and Meaker<sup>2</sup> estimates that there are two million childless couples in the United States who are still in the child-bearing age.

Sterility varies from that which is complete and absolute to that which is only relative or partial and which is amenable to improvement by treatment. In many matings the fertility factor is not fixed but rises or falls according to various conditions. Furthermore, a sterile mating may result from the union of two persons of rather low fertility, but each of these persons may be fertile when remarried to a new partner of high fertility. Thus sterility is frequently not the fault of one partner only but is often due to the sum total of several minor faults in both partners, each of which taken by itself might not amount to much, but

Read before the Section on Urology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

2. Meaker, S. R.: *Human Sterility*, Baltimore, Williams & Wilkins Company, 1934.

all of which added together cause the couple to be sterile. The secret of successful treatment lies in finding and correcting these faults.

For the purposes of this symposium on sterility I shall limit myself to a discussion of only the endocrine factors in sterility. Recent developments have been so enormous and rapid in the field of endocrine action in relation to human reproduction that to give a complete review of this very complicated subject, especially in a short paper such as this, is absolutely impossible. Furthermore, many points are as yet extremely puzzling and confusing, and therefore I shall have to limit myself to giving a brief general outline of some of the major features that seem to have been pretty well established.

Given a nonfertile mating in which thorough examination of both partners reveals no structural reason for sterility, there arises the question of an endocrine cause. It is well known that endocrine disturbance is a frequent cause of sterility. The late Allan Rowe over a period of many years studied about 4,000 patients from the endocrine point of view, and he and Lawrence<sup>3</sup> found definitely more sterility in the endocrinopathic patients than in the nonendocrinopathic patients and felt that a history of sterility suggested the possibility of an endocrine disturbance. Meaker<sup>2</sup> found that about 57 per cent of all his sterility patients showed some evidence of endocrine disturbance.

Although sterility occurs in such extreme endocrine abnormalities as gigantism, acromegaly, pituitary dwarfism, Simmonds' disease (pituitary cachexia), cretinism, Addison's disease and tumors of the adrenal cortex, I shall not discuss such cases, because in the great majority of them fertility is not their chief concern and also because such cases are so extreme that the diagnosis of some major endocrine disaster is obvious. I shall limit my discussion to the somewhat less striking type of endocrinopathy, in which the patient is apt to come to the urologist's office first complaining of sterility.

It is becoming increasingly apparent that the anterior pituitary is the most important and dominant member of all the endocrines—the master gland, so to speak—and that it influences and controls their actions, although it is reciprocally affected by them.

Although it is probable that insufficiency of the anterior pituitary during adolescence is responsible for most of the disorders of the other endocrine glands leading to sterility, in many adult patients, seen by the physician, complaining of sterility in marriage, the abnormal pituitary action is over, leaving some secondary result presenting—for example, hypoplastic ovaries—as the chief obvious endocrine fault at the time of examination.

Clinically there are three glands, disorders of which are mainly responsible for most endocrine sterilities—the anterior pituitary most frequently, the ovary and the thyroid—and it is with these three that I shall deal.

The anterior pituitary, the "master gland," controls the other endocrine glands and in both sexes influences the gonads, which operate under its control. The gonads have a double function: first, the production of essential germ cells and, second, the production of hormones or internal secretions that control the accessory reproductive organs and characteristics. The anterior pituitary stimulates each of the two functions of the gonads in the two sexes with a separate hormone. The follicle

stimulating gonadotropic hormone of the anterior pituitary stimulates predominantly the germ cell line and thus stimulates ovarian follicle formation in the female and spermatogenesis in the male. The second gonadotropic hormone is the luteinizing hormone, which stimulates the theca cells of the ovaries to luteinization and the interstitial cells of the testis. Therefore it is not surprising that removal or destruction of the anterior pituitary results in degeneration of ovaries and testes and in failure to produce germ cells or hormones.

As a result of the action of these two hormones on the ovary, two ovarian hormones are produced. The follicle-stimulating hormone brings about follicle formation, which produces the ovarian hormone estrogen, and the luteinizing hormone causes luteinization with formation of the ovarian hormone progesterin. Thus in the pituitary-ovarian relationship there are two pituitary hormones and two ovarian hormones, the presence or absence of which can be determined by biologic tests.

When it comes to the testis it is known that the anterior pituitary hormones stimulate the testis to the production of at least one testicular hormone. At present there is a great question as to whether two testis hormones are produced just as in the case of the ovary. There is some evidence in favor of a second testicular hormone, but the question is not yet settled and the entire testis hormone situation is not so clear as that of the ovarian hormones.

It has been found that in both sexes the injection of gonad hormones not only does not stimulate the gonads which produce them but is even injurious to them. This is an important therapeutic point and is in accordance with the principle that no endocrine gland is stimulated by products which it itself produces—a most important fundamental principle. There is a reciprocal interaction between the gonads and the anterior pituitary, so that an increase in gonad hormone decreases the gonad-stimulating activity of the pituitary and, vice versa, a decrease in gonad hormone is accompanied by an increase in the gonad-stimulating power of the pituitary. Thus the deleterious effect of the injection of gonad hormones on the gonads themselves has been interpreted as being due to inhibition of the pituitary hormones necessary for the normal maintenance of the gonads.

Therefore, the administration of estrogenic substance or the active principle of the testis is not only not beneficial but is injurious to the ovaries or testes themselves and is contraindicated in cases of sterility. The only exception to this rule is in cases of habitual abortion, which is, so far as the end result goes, a cause of sterility. On account of animal experiments which showed that removal of the corpus luteum caused abortion, the hormone of the corpus luteum, progesterin, has been used<sup>4</sup> with some success in cases of threatened and habitual abortion, on the basis that they might be due to a deficiency of natural progesterin.

The relationship between the anterior pituitary and the gonads is such that, while proper function of the gonads may be prevented by inadequate secretion of the pituitary hormones, in some cases these hormones may be produced in normal amounts, but the defective gonads fail to respond to them. One can thus speak of primary hypogonadism in cases in which tests show

<sup>3</sup> Moore, C. R.: Hormones in Relation to Reproduction, *Am. J. Obst. & Gynec.* 29:1 (Jan.) 1935.  
<sup>4</sup> Krohn, Leon; Falls, F. H., and Lackner, J. E.: On the Use of the Lutein Hormone, Progesterin, in Threatened and Habitual Abortion, *Am. J. Obst. & Gynec.* 29:198 (Feb.) 1935.

<sup>2</sup> Lawrence, C. H., and Rowe, A. W.: Studies of the Endocrine Glands, *Endocrinology* 13:108 (July-Aug.) 1929.

plenty of gonadotropic hormones present but the gonads themselves are at fault, and of secondary hypogonadism which is due to defective production of hormones by the pituitary.

Therefore, from a therapeutic point of view the gonads in secondary hypogonadism, proved by biologic hormone tests, are best activated by pituitary gonad-stimulating hormones and not by gonad hormones.

Biologic hormone tests, of which the Aschheim-Zondek pregnancy test is a good example, represent a great advance in diagnosis in cases of sterility. At the present time by means of injections into rodents or monkeys of extracts from blood<sup>6</sup> or urine<sup>7</sup> and by endometrial biopsy<sup>8</sup> one can arrive at a pretty accurate estimation of the four hormones in women, the follicle-stimulating and the luteinizing hormones of the anterior pituitary and the two ovarian hormones, estrogen and progesterin. This is a very important advance indeed, because it allows one to find out rather accurately the exact endocrine situation. Many cases that clinically appear alike are really very different endocrinologically and, in the absence of determining clinical signs, hormone tests are the only way of distinguishing, for example, between an amenorrhea due primarily to ovarian deficiency and one in which the amenorrhea is due primarily to failure of the pituitary to stimulate the ovary. The testis hormone in males can probably be best demonstrated by the effect on the comb growth of capons and also by the effect on the accessory genitalia of rodents.

In dealing with sterility of probable endocrine origin it is very important to find out which gland of internal secretion is primarily responsible in order to give intelligent treatment. This must be accomplished by a combination of clinical and laboratory observations, since either alone might lead one astray; for example, both thyroid deficiency and pituitary deficiency may result in obesity.

As I mentioned before, of the three glands hypofunction of which is responsible for most of the endocrine sterilities, much the commonest is anterior pituitary hypofunction, which may be either functional or due to pathologic damage. Coincidentally with this there may be hypofunction of the posterior lobe giving rise to bilobar failure of the pituitary, or there may be normal or increased function of the posterior lobe causing pituitary dysfunction. Probably the commonest pituitary type encountered clinically is a mild Fröhlich's adiposogenital dystrophy. Another pituitary cause of sterility in both sexes is the pituitary basophilism-adrenal cortex syndrome, the pathogenesis of which is not yet clear. It appears possible that it is the basophil cells of the anterior lobe which may produce the gonadotropic hormones.

In cases of hypofunction of the anterior pituitary, the signs and symptoms may differ according to whether bilobar failure or pituitary dysfunction is present, but there is a basic pattern to which all variations are apt to conform in a general way. Evidence of genital and ovarian hypoplasia is present. There is usually the history of the delayed appearance of puberty and later, in women, increasing intervals between periods with

constantly less menstrual flow, progressing to amenorrhea. Some patients show extremes of stature, being either very tall or very short. Obesity, especially of the so-called girdle type, is very common. The hair may be scanty or may show a heavy overgrowth. The visual fields are apt to be disturbed. Laboratory examination is apt to disclose a moderately lowered basal metabolic rate. Tests show increased sugar tolerance in bilobar failure but a decreased sugar tolerance in pituitary dysfunction if the posterior lobe is hyperactive. The blood uric acid is raised. The specific dynamic action of protein is lowered, according to Goldzieher and Gordon.<sup>9</sup> Biologic tests show the absence of anterior pituitary gonadotropic hormones.

As causes of sterility secondary in importance to the anterior pituitary and yet potent factors come primary hypofunction or dysfunction of the ovaries, and hypothyroidism.

In sterility that is due to inherent faulty function of the ovaries themselves quite independent of any secondary effects from any other gland such as pituitary or thyroid, there is often the history of easy fatigability and headache, and usually great nervous instability. There is no characteristic habitus, but the genitalia are apt to be hypoplastic. Menstruation is sometimes normal but more often irregular and scanty, and dysmenorrhea is common. The biologic hormone tests show absence of ovarian hormones but increased anterior pituitary gonadotropic hormone, probably the result of compensatory hyperactivity of the pituitary in an effort to stimulate the sluggish ovary.

Another ovarian cause of sterility is the condition of anovulatory menstruation, of which there has been considerable mention made recently. This has been described by Novak<sup>8</sup> as follows: Just after menstruation the graafian ovarian follicle begins to mature and produce increasing amounts of estrogenic substance in the normal manner. However, for some reason it does not rupture but keeps on beyond the stage of usual maturity, until the ovum dies, the granulosa degenerates, production of estrogenic substance ceases and finally, after an interval, bleeding occurs. Thus there is produced a periodic bleeding which looks like normal menstrual bleeding but in which the patient is sterile because there are no ova. The diagnosis can be made by microscopic examination of the endometrium obtained by a biopsy curet shortly before an expected flow. In the normal woman there is at that time present in the ovary a functioning corpus luteum producing progesterin and bringing about the characteristic secretory phase of the endometrium. If, however, the endometrium shows only proliferative endometrium, with no evidence of secretion, it can be concluded that there is an absence of progesterin because of the absence of a functioning corpus luteum in the ovary and that therefore ovulation has not occurred.

In sterility due to hypothyroidism there is general sluggishness of the whole organism with a tendency to overweight. Hair is scanty and there is a tendency to skin diseases and constipation. The basal metabolic rate is depressed, the blood cholesterol is raised, and in extreme cases the typical signs and symptoms of myxedema are present. Menstruation is characteristically erratic, the amount of flow varying from scanty to very profuse, and the length of time between periods varying in an irregular and erratic way.

Undescended testicles are a potential cause of sterility; it has been shown that if they are still undescended after puberty they will in most cases irreparably have lost their ability to produce spermatozoa. This makes it imperative to have the testes in the scrotum before puberty. In the last few years there have been many reports of the bringing about of the descent of undescended testicles by the administration of gonadotropic substance. In almost all these cases the principle used has been the anterior pituitary-like substance of pregnancy urine. There seems to be no doubt of the efficacy of this in many cases, but the action is erratic and inconstant and, if the testes do not come down after a reasonable course of treatment, surgery is to be preferred to a prolonged series of treatments, which conceivably might have disturbing endocrinologic consequences.

#### THERAPY

In spite of the remarkable advances made in reproductive physiology there is still uncertainty on many points, so that it is not surprising that the therapeutic applications of these new advances are not yet altogether clearly defined. In general, the treatment of endocrinopathic sterility has not been very successful. Part of this has been due to ignorance of the exact physiology and pathology involved, so that various gland extracts have been used indiscriminately on the basis of a vague hope that extracts of organs obviously related to reproduction and pregnancy might somehow benefit sterile patients and increase their fertility. From the point of view of intelligent and effective treatment it is of fundamental importance in any given case to arrive at an accurate diagnosis of just which endocrine link is missing or at fault. For example, the administration of the pituitary gonad-stimulating principle is of absolutely no use whatever if tests show that the patient's own pituitary is already producing an excess of these to which the ovary will not respond.

In accordance with the fact that the administration of products made by the gonads not only does not stimulate them but has even been shown to injure them, the use of ovarian substance or of the two ovarian hormones, estrogenic substance and progestin, and of testis hormone is contraindicated in cases of sterility. The only exception to this rule is the use of the corpus luteum hormone, progestin, in cases of threatened or habitual abortion, already referred to.<sup>5</sup>

In cases in which the tests have shown the absence of anterior pituitary hormones their use is rational. It is very doubtful whether pituitary preparations given by mouth are effective at all. To date the hormones as obtained from the anterior pituitary itself have not been generally available. The first of the pituitary gonadotropic substances to be put on the market commercially and the one which has had a great vogue and has been used widely is the luteinizing factor, obtained from pregnancy urine. This is called the anterior pituitary-like gonadotropic substance. This is not an entirely pure hormone product, but its general effect is to stimulate the interstitial cells of the testis and to stimulate the theca cells of the ovaries to luteinization. The other anterior pituitary gonadotropic hormone has been available commercially for so short a time that few clinical results with it have been reported as yet. This hormone is obtained in comparatively pure form from castrate or menopause urine and is the follicle-stimulating fraction that stimulates the ovaries to follicle formation and the production of estrogenic substance and the testes to spermatogenesis.

Ovarian or testicular hypoplasia is usually due to the failure during adolescence of the necessary endocrine stimulus of the anterior pituitary. At the end of adolescence the genital developmental impulse usually stops and in most cases can never be reactivated by any endocrine treatment. Therefore, if pituitary failure has occurred during adolescence and the testes or ovaries have never developed and are markedly hypoplastic, usually nothing can be done for such patients when they are adults, because it is too late and the developmental impulse is permanently gone. However, the degree of hypoplasia may vary, and cases in which the hypoplasia is not marked are not necessarily beyond hope, even in adults, and are worth a clinical trial with gonadotropic pituitary hormones. Were such patients treated with gonad-stimulating pituitary preparations during adolescence, before it was too late, much might be done for them.

Furthermore, in sterile adults in whom the tests show absence of pituitary hormones a trial with them would seem worth while, as there is nothing to lose and everything to gain.

In amenorrhea due to hypopituitarism and in Frölich's adiposogenital dystrophy, therapy with luteinizing substance from pregnancy urine alone has been disappointing. This is not surprising in view of the fact that in many of these cases genital hypoplasia is so far advanced as to be beyond salvage, as already mentioned, and also in view of the fact that it is the other, the follicle stimulating, principle, only recently available commercially, that is theoretically the proper one to use to stimulate graafian follicle formation and spermatogenesis. In view of this last fact it is puzzling that stimulation of spermatogenesis following injections of the luteinizing factor has been reported by a few workers.<sup>10</sup> It would be interesting to see whether this could be consistently confirmed in a large series, as its use has been disappointing to me and also to others.

The simultaneous administration of both the follicle stimulating and the luteinizing factor has been shown to have a much greater effect than the simple sum of one added to the other and is referred to as the principle of augmentation or synergism. Therefore at the present time the simultaneous administration of both the follicle stimulating and the luteinizing factor would seem to be the best way to administer pituitary gonadotropic principles in cases of gonadal hypofunction, which have been shown by biologic tests to be secondary to anterior pituitary failure.

Another form of treatment in pituitary gonadal sterility is stimulating roentgen therapy directed to the pituitary and the gonads. Some esteem this treatment very highly and report good results<sup>11</sup> in increasing fertility in many cases.

Last, but far from least, the oral administration of thyroid is indicated in all cases presenting even a low normal metabolism, and obesity. In some way it also seems to act as a most valuable adjuvant in pituitary-gonad cases, possibly because it activates sluggish bodily processes. It is one of the most valuable aids in sterility, either alone or in combination with other therapy.

## CONCLUSIONS

1. Much of the treatment of endocrine sterility in the past has been unsuccessful partly because miscellaneous gland therapy was used indiscriminately, based on vague hopes rather than on science.

2. Clinically there are three glands, the hypofunctioning of which are mainly responsible for most endocrine sterilities—the anterior pituitary most frequently, then the ovary and the thyroid.

3. In dealing with sterility of probable endocrine origin, it is of fundamental importance to find out by means of both clinical and laboratory observations, including biologic hormone tests, which gland is primarily responsible, in order to give the proper treatment intelligently and effectively.

4. The therapeutic injection of gonad substance not only does not stimulate the gonads but injures them and is contraindicated in sterility.

5. At the present time the simultaneous administration of both pituitary gonadotropic principles would seem to be the best form of therapy in cases of gonadal hypofunction which have been shown to be secondary to failure of the anterior pituitary.

6. Thyroid extract is a very valuable aid to the treatment of sterility.

7. Since nothing can be done for sterile adults with markedly and completely hypoplastic testes and ovaries, it is desirable for adolescents who present any endocrine symptoms, such as delayed appearance of the catamenia, to consult a physician and have treatment before it is too late and the developmental impulse is exhausted.

8. The therapy of endocrine sterility is not yet clearly defined in every way. However, in the last few years scientific progress has been made and more will undoubtedly follow in the near future.

## ABSTRACT OF DISCUSSION

DR. MOSES SWICK, New York: Our knowledge concerning the sex cycle in the female is more clearly defined and advanced than in the male, perhaps because of more accessible methods of attack for investigation or because of the underlying differences in physiologic response in the two sexes. As Frank states, "in the healthy adult female a cyclic activity of the pre- or anterior pituitary is manifested by the cyclic blood and urinary curves. In the male there is no evidence of a pre-pituitary cycle or of a senile condition corresponding to the menopause." The testis hormones have been demonstrated in the urine. No cycle has been found and little correlation between functional diseases and changes in the humoral balance as yet has been discovered. Organic disease in the male can produce changes in the excretion of the gonadotropic principle. In the problem of sterility it may be theoretically necessary to deal not alone with the question of proper hormone selection for a given case but with the added difficulty of antihormone formation to the specific hormone as stressed by Collip, which may account for a state of supposed refractoriness. As stated by Moore, in the male, testis hormone is secreted continuously or periodically in different animals, secretion being largely under the influence of the anterior pituitary. It is not a testicular stimulant. Its primary function is the control of the accessory reproductive organs. The synthesis by Ruzicka and his co-workers recently of the pure male hormone testosterone, which belongs to the family of sterols, is a chemical achievement of great importance. Biologically it has been shown to induce the characteristic comb changes in the capon and growth of the accessory reproductive organs of the mammal. These compounds when they become commercially available may theoretically prove to be of value either alone or in conjunction with proper anterior pituitary hormone therapy in certain types of sterility. However, as pointed out by Dr. Chute, testis hormone injections of sufficient concentration may be injurious to the gonad tissue.

## THE SMALL INTESTINE

EUGENE P. PENDERGRASS, M.D.

PHILADELPHIA

Clinicians are beginning to attach some importance to the roentgen study of the small intestine. Relatively little investigative work has been done on this portion of the digestive tract by radiologists, and because of this the interpretation of lesions of the small intestine is much more difficult than of other portions of the gastrointestinal tract. Consequently, only obvious lesions have been diagnosed. The difficulty of diagnosis, it seems to me, presents a challenge to those of us interested in this viscus. To accept this challenge, it is essential that collective studies be made of the small intestine in healthy individuals and in patients having lesions of the small intestine. It is well known that lesions involving other portions of the gastro-intestinal tract as well as conditions outside of it may exert a profound influence on the mechanics and pattern of the small intestine. Any investigation, therefore, should include a careful consideration of all such factors.

The small intestine has been amenable to being adequately studied by physiologic, chemical and roentgen methods in most instances, either individually or simultaneously, since the development of intestinal intubation by Miller and Abbott.<sup>1</sup> All methods are tedious and time consuming and considerable additional investigation will be necessary before such studies will be practical as routine procedures in gastro-intestinal examinations. It would be ideal if our knowledge of the small intestine in health and disease would progress to such an extent that it would be possible to correlate certain symptom complexes with lesions of this tract and roentgen studies be employed with the assurance that roentgenologists could affirm or disprove the presence of a lesion of this portion of the bowel. At any rate, with increased experience our ability to recognize abnormalities in the small intestine is improving. It is felt that the small intestine is the site of many more lesions than have been attributed to it by roentgenologists and clinicians. Many lesions of the small intestine undoubtedly have been attributed to neurosis because of failure adequately to study the entire gastro-intestinal tract.

In previous papers my associates and I<sup>2</sup> have presented a plea for a standard meal, so that one radiologist may compare his results with those of another. Our observations<sup>2a</sup> indicate that the pattern of the small intestine will vary considerably, depending on the composition of the foodstuff it receives. It varies also with the consistency of the meal, its size, the gastric emptying time and the tonicity of the intestinal tract. Furthermore, data have been collected by ourselves and others which indicate that certain pathologic conditions which only indirectly affect the intestinal tract may cause a very profound change in the small intestine pattern. Furthermore, if radiologists are to

assist in the study of food allergy and its effects on gastro-intestinal motility and pattern one must have a base line from which to draw comparisons.

The meal that we use consists of 5 ounces (140 Gm.) of barium sulfate and 5 ounces (150 cc.) of water. Such a meal has the consistency of a thick pabulum but allows excellent visualization of the mucosal pattern. The normal stomach empties such a meal in the majority of instances within two hours; occasionally the period is as long as three hours. The small intestine stream is continuous with little if any regurgitation or peristaltic rushes. In the beginning the jejunal pattern has a somewhat obscured herringbone appearance. As the meal passes distally the herringbone pattern becomes more evident and this is followed by a feathery, snowflaked pattern, the latter being due to retained barium in the vasa digestiva. Usually no central lumen is discernible in the jejunum. There is a tendency for the jejunum to have segmental contractions, which have been interpreted as being due to circular and longitudinal muscle contractions. In such areas the pattern tends to form longitudinal folds. Elsewhere in the jejunum the folds are transverse. Occasionally one sees a wavy appearance, which is probably due to rapid motility at the moment. In the ileum the pattern is frequently that of a series of small irregular boluses. Occasionally the mucosal pattern is seen and suggests coins placed one on the other. The intermucosal space is usually wider than that seen in the jejunum. No gas is ever found in the small intestine of the normal individual.

The head of the column reaches the cecum occasionally in one and one-half hours. In most instances it requires from two to three hours to reach the cecum and from four to six hours for the intestine entirely to empty itself. Under control circumstances the small intestine motility is so gradual that most careful observation is necessary to detect peristaltic movements, segmental contractions and changes in the mucosal pattern. We believe this is extremely important, and when these phenomena are apparent at a glance, we immediately assume that there is something abnormal. On one occasion in a healthy control the small intestine motility was very rapid, the head of the column reaching the cecum within thirty-five minutes. These phenomena are similar to those seen after the administration of magnesium sulfate. We are unable to account for this. I have seen this before in patients who stated that there occurred abdominal cramps after taking barium sulfate whereas under the conditions usually imposed on the gastro-intestinal tract no such symptoms are present.

The exact length of the small intestine during life is not known. It is generally agreed that the upper three fifths of the small intestine consists of the jejunum and that generally this lies to a large extent in the left side of the abdomen. The jejunum, or "hungry gut," is larger in diameter than the ileum, the diameter of the small intestine normally decreasing from the duodenal jejunal flexure to the ileocecal valve.

The lumen of the small intestine as a whole seems to be smaller in fat individuals as compared to thin. I have an impression also that there is a difference in the size of the intestine in men and in women, but further control studies are necessary before making a definite statement.

The small intestine not only plays a major rôle in preparing foodstuffs for digestion but it also is the portion of the gastro-intestinal tract which is most

active in the absorption of the products of digestion. Forssell<sup>3</sup> and Cole<sup>4</sup> believe that, during digestion, digestive compartments and digestive alveoli referred to as a feathery snowflaked pattern are formed as a consequence of what they have termed the autoplasty of the mucous membrane. A variety of patterns of the small intestine may result not only from variations in the muscle tonus but also in rearrangements of the mucous membrane folds.

The examination of the small intestine requires several hours as a rule, and occasionally its physiologic function has been disturbed as a result of the patient having developed a headache because of food being withheld. We have also been unable to determine what part psychic or emotional disturbances may take in influencing the small intestine motility and pattern, but we have reason to believe that fear is occasionally a potent factor.

The thick meal in our experience does not cause any increase in the frequency of impaction. If one fears this, a laxative or dose of liquid petrolatum after the completion of the examination should prevent one from developing an impaction. The taste is bland and there are no more complaints of this than of other mixtures.

Normal variations and anomalies occur more frequently than was anticipated, and, as elsewhere, the variants will probably occur in a frequency proportional to the thoroughness of the examination and one's ability to detect them.

Very small diverticula (from 1 to 3 mm.) as well as larger ones are not uncommon.

The finding of the small intestine on the right side of the abdomen is usually associated with a left-sided colon.

Retroperitoneal herniation of the small intestine may be recognized by the fact that usually it may form a conglomerate mass in the middle of the abdomen and motility may be delayed considerably.

Occasionally the position of the small intestine (riding over the colon) is such that it may lead to the development of a megacolon and occasionally to obstruction.

We have studied a variety of intrinsic lesions that will affect the pattern and motility of the small intestine, many of which have been previously described by other authors. These include tumors of the small intestine, worms, obstruction, ileitis, tuberculosis, nephrosis, primary jejunal ulcers (individuals in whom a gastro-enterostomy has not been performed) and secondary jejunal ulcers.

Intussusception of the small intestine may occur in any portion of the intestine. Small intrinsic tumors have been present in the two instances in which we have observed this phenomenon in the jejunum.

Radiologists have been called on by some to diagnose the point at which the intestine is obstructed. We have been impressed with the number of variants from the position of five groups of small intestine coils described by Cole.<sup>5</sup> We have noticed a marked difference between two different examinations in the same individual and because of this we feel that the radiologist should be extremely careful in identifying for the surgeon the point of obstruction in the small intestine.

5. Cole, L. G.: *Exploration of the Mucosa of the Gastro-Intestinal Tract*, Saint Paul and Minneapolis, Bruce Publishing Company, 1934.

Various drugs,<sup>6</sup> especially the sedative group, have a profound effect (delayed motility and small intestine gas) on the gastro-intestinal tract for at least twenty-four hours and in some instances as long as five days. The radiologist therefore should be careful to exclude a drug effect before making an interpretation of obstruction or delayed motility.

Other lesions that will disturb the normal physiology and that have received certain attention from the radiologist are extrinsic lesions such as tuberculous (mesenteric) lymph nodes and abdominal tumors. There is a group of abdominal lesions that will affect the small intestine reflexly. These include renal stones (with crises), gallbladder disease, adrenal tumors and retroperitoneal extravasations and infection. Retroperitoneal tumors and perinephric abscess, and possibly kidney infection, metastatic carcinoma and tuberculous peritonitis, in fact, anything that will give rise to peritoneal irritation, will disturb the physiologic function of the small intestine. The frequent complaint of abdominal discomfort with gas can be explained in a great many instances by disturbed function of the small intestine and has been misinterpreted by all patients and many physicians.

Extra-abdominal lesions may also affect the small intestine. These include hyperthyroid and hypothyroid disease. We have made a collective study of twenty-five patients before and three months after operation. The results of this study are being prepared now. Pituitary and brain tumors, diabetes insipidus, tabes, neurocirculatory and cardiac disease and spinal cord lesions will profoundly affect the physiology of the small intestine. It is necessary, therefore, to bear these conditions in mind in evaluating the x-ray observations.

3400 Spruce Street.

#### ABSTRACT OF DISCUSSION

DR. HARRY M. WEBER, Rochester, Minn.: Dr. Pendergrass and his collaborators deserve praise for the excellent work they are continuing on the anatomy and physiology of the small intestine. Hitherto this field of roentgenologic diagnosis has been somewhat neglected, but the work of these men has been richly informative and stimulating, and we who are particularly interested in gastro-enterologic roentgenology do well to commend and to encourage continued efforts along these lines. At the suggestion of Dr. Pendergrass I take the liberty of extending his discussion to remark briefly on the roentgenologic manifestations of pathologic processes affecting the small intestine. Like the colon, the small intestine is a tubular organ, and, in their morphology and pathogenesis, the pathologic processes which occur in the small intestine are similar to those which occur in the colon. Thus there are tumefactive processes which may be neoplastic, e. g., carcinoma, sarcoma and benign tumors, or non-neoplastic, e. g., tuberculoma and other tumor-producing inflammatory processes. More or less diffuse ulcerative processes occur as well, such as tuberculous enteritis and the enteritis (ileitis) to which Krohn and his collaborators called attention. Certain deficiency diseases are manifested by roentgenologically demonstrable morphologic changes in the small intestine. Finally, the small intestine is relatively frequently involved secondarily by pathologic processes, especially tumors, of neighboring and contiguous organs, deforming it segmentally either by direct extension and invasion or by producing a trophic type of ulceration into its lumen. From typical examples it is plain that lesions of the small intestine are demonstrable roentgenologically and that a satisfactory differential diagnosis can be elaborated by using the principles proved sound through long experience in the roentgenologic diagnosis of diseases of the large intestine. The

roentgenologic examination of the small intestine is difficult only because its relatively complicated anatomic arrangement makes the necessary close roentgenoscopic and roentgenographic scrutiny of each small portion of its entire length seem comparatively arduous and time consuming, and because its rapid and involved motility may produce a variety of peculiar and quickly changing mucosal patterns, not to be too readily endowed with pathologic significance.

DR. E. V. POWELL, Temple, Texas: This report of pathology of the small intestine is very valuable. I hope to avoid repeating an error I made a number of years ago in examining a patient who complained of symptoms indicative of obstruction in the lower small intestine. I reported no lesion found. About a year later the patient was again examined, at that time by barium sulfate enema. From the second examination I reported a small malignancy near the apex of the sigmoid. At operation a primary carcinoma of the ileum that involved the adjacent sigmoid by direct extension was found. I doubtless had missed it the first time I examined the patient.

#### SEASONAL HAY FEVER AND ASTHMA DUE TO MOLDS

SAMUEL M. FEINBERG, M.D.

Assistant Professor of Medicine, Northwestern University Medical School; Attending Physician, Cook County Hospital  
CHICAGO

In a previous report it was shown<sup>1</sup> that the non-pathogenic spores of molds found in the air are frequent causes of asthma and nasal allergy. Thus far no emphasis has been placed on the fact that these symptoms frequently assume a seasonal character and become confused with pollen hay fever and asthma. It is my purpose in this paper to call attention to a group of patients whose respiratory manifestations are confined to the summer or aggravated in that season by sensitiveness to fungi instead of pollen.

Over a period of several years, impressions gained from clinical and laboratory observations with respect to seasonal hay fever and asthma culminated three or four years ago in the belief that these symptoms are not always due to pollen. The fact that there are many patients who respond only partially or not at all to pollen treatment led to the suspicion that something additional might be found with regard to the etiology. Since it has been repeatedly established that in pollen hay fever the symptoms vary almost directly with the height of the pollen count, it was perplexing to encounter patients whose symptoms did not at all agree with the daily pollen determinations. The histories of some of these patients were either not as definite with regard to the onset or cessation of symptoms as they are customarily found in pollen cases or the symptoms overlapped the season at both ends. Negative or questionable skin and mucous membrane tests with pollen constituted another disturbing observation. And finally, while pollen counts were being made, summer after summer, the spores of molds and rusts were being encountered on the slides. These occurred in such large numbers at times that one could not help but speculate on the possible rôle they might have in the causation of hay fever.

(Continued from page 1861)

It is necessary to call attention at this point to the fact that the conception of fungi as causes of respiratory allergy is not new. Van Leeuwen<sup>2</sup> of Holland and later Hansen<sup>3</sup> of Germany stressed the importance of nonpathogenic fungi in asthma. Cadham<sup>4</sup> in 1924 described asthma due to rusts. Molds as causes of asthma were not reported in this country until 1930, by Hopkins and his co-workers<sup>5</sup> and by Bernton.<sup>6</sup> As a matter of fact, Blackley,<sup>7</sup> experimenting on his own hay fever about seventy years ago, described a nasal and bronchial reaction having all the earmarks of allergy, on inhaling mold spores. He concluded, however, that this had nothing to do with the cause of hay fever. Had he not chosen to ignore this experiment, our knowledge of that subject would probably not have been dormant for so many years. Since 1930 a number of papers dealing with mold allergy have appeared. Until recently the instances of mold allergy reported were described as more or less medical curiosities; i. e., unusual cases due to exceptional environmental sensitizations, such as a moldy mattress, a musty basement or similar special exposure.

Fig. 1.—Magnified field on glass slide which has been exposed outdoors for pollen counting. Note the pollen and also the fungus spores. a, ragweed pollen; b, *Alternaria* spores; c, other spores, probably *Hormodendrum*.

My own point of view has been somewhat different. Since mold spores are present in the outdoor air in greater numbers than in indoor air, as shown by culture plate and slide studies, they are to be regarded as possible causes of allergy in every individual. Thus encouragement was given to make a wider selection of mold extracts for sensitization studies and to conduct such studies in a routine manner on allergic patients. In this way it was possible to uncover a large group of fungus-sensitive patients, thus elevating the fungi to a high place in the scale of important allergens. The results of part of this work have been previously reported.<sup>1</sup>

Later, after the importance of mold allergy in general had become recognized, it became evident that many of these mold-sensitive individuals had seasonal ten-

dencies; i. e., their symptoms were confined to the warm months or aggravated at that time. Our studies<sup>1</sup> on the mold content of the air by means of daily culture plates for almost two years along with our previous slide studies have corroborated our conception of the presence of a seasonal group of hay fever and asthma patients whose symptoms are due to molds. It might be mentioned that in the presentation of fungus-sensitive patients by Bernton,<sup>6</sup> Brown,<sup>9</sup> and Underwood,<sup>10</sup> seasonal aggravation is mentioned in some of the case reports but the possible importance and significance of this is not made apparent.

#### CLINICAL OBSERVATIONS AND "SEASONS"

From the records of private patients there have been selected fifty-four who can be classed into a distinct group. These individuals have hay fever or asthma, or both; their symptoms are either entirely confined to the warm months or are aggravated during that period; and it can be demonstrated that fungus spores play a part in the causation of their symptoms. Mold-sensitive patients who have no seasonal variations have not been included in this group. Neither have been included any individuals whose seasonal variations in symptoms could not be definitely ascribed to fungi although they reacted to the latter. It is true that of the fifty-four patients very few are sensitive to fungi alone. It is also admitted that the majority of these individuals had varying degrees of difficulty during the winter months. In this respect, however, this group does not differ materially from the pollen group. Many of those who present themselves for hay fever management have symptoms during the nonpollen months and the majority of them are sensitive to other allergens in addition to the pollen. Nevertheless, these patients are classified primarily as having hay fever. In the same sense there is reason to regard these seasonal mold-sensitive patients as a distinct group.

The evidence for the claim that in this group seasonal hay fever or asthma is caused by sensitivity to the air-borne spores of fungi may now be briefly analyzed:

1. All these patients have positive skin tests to fungi. The extracts are made from pure cultures of atmospheric molds. With the exception of two patients, all positive diagnostic tests were obtained by the scratch technic. Usually reactions to more than one type of mold were obtained. The accompanying table shows the reactions to a few of the most important of these fungi.

2. In most of the instances in which it was tried, a positive Prausnitz-Küstner reaction was obtained. The site of skin of a normal individual injected with the serum of the patient reacted specifically to the suspected mold, while the skin of the other arm failed to react. This demonstrated that the original reaction on the patient was in no sense a nonspecific or "false" reaction.

3. The majority of these patients, on careful inquiry, gave a history of a "season" which either did not agree with their individual pollen reactions or with any pollen season. This is evident when the table is studied. It is to be remembered that most of the cases reported

ere are from around the Chicago area. The important pollen seasons there are usually as follows: trees, April and May; grasses, May 15 to July 15; ragweeds, August 10 to September 20. Thus it is evident, for example, that patient 26, who has hay fever from May to November and whose sole pollen reactor is ragweed, must be sensitive to something else, at least from May to August and from October to November.

4. In most instances there has been opportunity to observe these patients during the summer. Records of their symptoms have been kept and have been com-

Fig. 2.—Number of pollen grains and spores (*Alternaria* only) in the air every day during the midsummer of 1935 in Chicago. Solid line, *Alternaria* spores; broken line, pollen. These figures were obtained by examining the usual surface of the slide (1.8 sq. cm.) used for pollen counting. Note that from about July 15 to August 10 there was practically no pollen. At the same time there were great numbers of fungus spores. Patients who had marked symptoms during that period and milder symptoms earlier could certainly be suspected of mold allergy. (Reproduced by permission of the C. V. Mosby Company, from the *Journal of Allergy* 7:149 [Jan.] 1936.)

pared with daily analysis of the air with respect to pollen and mold spore content. It was definitely established that these individuals are really affected by the mold spores in the air. This was not always easy to do, since the same weather factors tend to influence both the pollen and the mold content in the same direction. However, there is a discrepancy at times which makes clinical interpretation possible. For example, in the summer of 1935 there was practically no pollen in the Chicago air from July 18 to August 10, but the mold spore count was high (fig. 2). These patients had considerable trouble during that period and their clinical sensitivity to fungi could be corroborated. There were a number of other periods when such opportunity for the separation of pollen and mold factors presented itself.

5. A number of these patients had been previously treated by others with pollen extracts with either complete or almost complete failure. I also had the experience of treating a few of these patients with pollen, with no improvement.

6. A few patients experienced systemic reactions during the course of mold desensitization.

7. The results of desensitization with mold extracts in about half of this group indicate a specific clinical effect. Many of these sufferers had received pollen treatments previously with little or no benefit.

As a matter of fact, these patients constitute so definite a group that recently it has been possible to surmise the true nature of the case in about three fourths of the instances on the basis of the history, before skin tests were made.

Now what constitutes a mold "season"? Strictly speaking, molds are never out of season. Viable spores have been found in the outside air every day of the year—even when the temperature ranged around 18 degrees below zero. For the 1934-1936 period in Chicago the intervals from December to March showed a minimum number of atmospheric spores. About April there begins a considerable increase in the number. July, August and September are possibly the worst months.

The "season" will depend, therefore, on the degree of tolerance of the individual. If his tolerance is fairly high, his symptoms might occur from July to October. If it is low, he may have symptoms from April to December. If as little as two or three spores per cubic yard of air will cause symptoms, the individual will have perennial symptoms. There also seems to be some differences in the prevalence of certain fungi at various times of the year. The particular fungi to which the individual is sensitive may modify his season.

What is said about seasons in this part of the country will not be applicable, of course, to remote parts. Preliminary samplings of the atmosphere from a few distant sections have shown tremendous differences. These studies are continuing in that direction, so that the results may be ultimately of help to physicians and patients in various localities.

Little will be said here about the actual causes of these symptoms—the molds. In this communication the discussion is limited to the nonpathogenic fungi the spores of which contaminate the air. These spores originate from the soil or from the fungi growing on decaying or living higher plants. It has been shown by a number of observers that these spores can be found at very high altitudes and at places very remote from their sources of origin. In our studies thus far<sup>8</sup> we may list the following genera among the most common fungi to which the individual is exposed: *Alternaria*, *Hormodendrum* (*Cladosporium*), *Penicillium*, *Monilia*, *Aspergillus*, *Chaetomium*, *Fusarium*, *Mucor*, *Rhizopus*, *Trichoderma*, *Cephalothecium* and *Actinomyces*. Yeasts are also quite common. From the standpoint of reactions in the group of patients presented *Aspergilli*, yeasts and *Alternaria* appeared to be most important, the latter reacting in practically every case. It is well to mention here that there have been a few patients

Fig. 3.—Seasons of asthma and hay fever due to fungi in fifty-four patients. The thickness of the blocks and the figures represent the number having symptoms during those particular months. For example, twenty-one patients had their season from May to October. Most of the patients also had slight symptoms during the winter months, but this is not depicted on the chart.

having all the characteristics of seasonal mold allergy, with negative skin reactions. Apparently there are other fungi or totally different antigens which it may be necessary to learn to recognize.

#### SPECIFIC TREATMENT

In this group of fifty-four patients with mold hay fever and asthma, twenty-eight were given desensitization therapy with appropriate mold extracts and observed during the season sufficiently so that the

results may be evaluated.<sup>11</sup> Eleven other patients were treated with mold extracts, but their treatment was begun late in the season so that the results cannot be ascertained at the present time. Among the twenty-eight patients who were given a fairly complete course of treatment, some were treated also with pollen. It is to be recalled that many of these patients had been treated with pollen previously with practically no benefit. However, the results of the mold desensitization can be evaluated by observation during the season, according to the indications outlined earlier in the paper. It is possible, therefore, to analyze definitely the effect that mold desensitization had in these patients. The results were as follows:

Eleven patients had from 90 to 100 per cent relief.  
Twelve patients had 75 per cent relief.  
Four patients had 50 per cent relief.  
One patient had no relief.

In this communication it is not feasible to go at length into a discussion of the technic of treatment. In general it may be said that it resembles very closely that of pollen treatment. The beginning doses are usually

Fig. 4.—The numbers of fungi as obtained from culture plates exposed to the outside air. The numbers represent the colonies on a standard size petri plate exposed for thirty minutes (two plates, fifteen minutes each) daily and averaged by the week. Only several groups of fungi were considered here. Note the preponderance of *Alternaria* and *Hormodendrum* in the summer and fall. January to May constitutes almost a closed season for these particular fungi. (Reproduced by permission of the C. V. Mosby Company from the *Journal of Allergy* 7: 149 (Jan.) 1936.)

about 0.1 cc. of the 1:10,000 or 1:100,000 of the mold extract, on the basis of the dry weight of the pellicle. The maximum doses at the end of the course of treatment have usually been a fraction of a cubic centimeter of 1:100. It is suspected that some of the patients require larger maximum doses for better results. It is likely that improvement in the results will occur when increased knowledge will make it possible to choose more accurately the antigens to be used in the individual case. Systemic reactions have been encountered just as in pollen therapy, indicating the potency of the material and the clinical sensitivity of the individual.

The following case reports will illustrate some of the salient features of this group of patients:

CASE 33.—Aug. 4, 1934, Avis G., a 30 year old assistant in the Department of Pathology, came to the clinic for her regular pollen treatment. On this particular morning she consulted us because of the marked asthma and hay fever from which she had been suffering. Her symptoms were intense. Her record showed that she was receiving almost a cubic centimeter

of each of the 1:33 extracts of ragweed and grasses. On inquiry it was definitely ascertained that no local reactions of any kind resulted from these pollen injections. The early and violent symptoms in spite of such intensive pollen therapy, together with the lack of any local reaction, aroused the suspicion that we were not treating the patient with the causal antigen. The records at the clinic showed negative skin tests to pollen. The previous season she had been given pollen treatments by a competent allergist with no benefit, although it is claimed that positive skin tests to pollen were obtained. Closer inquiry revealed the fact that her hay fever and asthma season was from April to November or December, with slight symptoms the rest of the year. Her maximum suffering was in July, August and September. These symptoms had been present for twenty-one years.

Fungi were suspected as a possible cause of her trouble and tests made showed very marked reactions, particularly with *Alternaria* and *Aspergillus*. Pollen reactions were entirely negative. Pollen treatment was discontinued and mold desensitization was begun. Marked local reactions were evident from the start and on two or three occasions sharp attacks of asthma occurred about twenty to thirty minutes after the injection. Treatment was continued through 1935 with at least 75 per cent relief. She says that it was the best summer she had ever had. She was not entirely symptom free, however, and close observation during the summer revealed the fact that her bad days coincided with marked increase in the mold spore content of the air.

CASE 29.—John B., aged 28, was seen July 13, 1934, with a history of typical hay fever symptoms of nine years' duration. His season was from April to October and at no time did he have symptoms in the winter except for one February, when he was in Cuba. August and September were his worst months. The previous summer he had had some sensitization tests, with negative results. Complete pollen tests made by us were entirely negative. This was followed by intradermal and conjunctival tests, which were also negative. Pollen allergy was definitely excluded. The patient was then tested with all possible allergens to which he might be exposed. A positive reaction to tobacco in no way explained the clinical picture. A one plus reaction was obtained to *Alternaria* by scratch test and a four plus reaction to a 1:10,000 intradermal solution. This was repeatedly confirmed. He was treated from April 13, 1935, to the fall of that year with an extract of *Alternaria*. Although the treatments were not very regular and the maximum dose not high, he estimates about 75 per cent improvement. His worst period was toward the end of July, when there was practically no pollen; at the same time it was the maximum period for the *Alternaria* count.

CASE 39.—Jack M., aged 8 years, was seen July 26, 1934, with the complaint of hay fever of four years' duration. The mother stated that his symptoms occurred from April until frost. A few days prior to his first visit he had had slight asthma. There were no symptoms in winter. Four years ago he had a tonsillectomy-adenoidectomy, which did not relieve his hay fever symptoms. The only member of the family known to have allergy was a great aunt who had asthma.

The nasal mucosa was typically allergic in appearance. The remainder of the physical examination was entirely negative. Cutaneous tests with a comprehensive assortment of allergenic extracts showed strong positive reactions to ragweed pollen, *Alternaria* and dust. There were no definite reactions to any of the other pollens or other variety of allergens. The fall hay fever could, of course, be explained on the basis of ragweed sensitiveness. The earlier symptoms and the marked symptoms in the latter part of July when practically no pollen was in the air constituted presumptive evidence for the fungi (*Alternaria*) as a cause. Treatment was begun with ragweed and *Alternaria* extract, one injection being given in each arm at every visit. His symptoms improved somewhat during the fall of 1934. His treatment was continued perennially. During the spring of 1935 he was improved. In July he began to have some moderate systemic reactions from the injections. By alternating the pollen and mold treatment at each visit it was found that the latter was responsible for the reactions. The dose was then reduced. The greater amount of hay fever symptoms occurred during the latter part of July. He had practically no discomfort the rest of the season. The mother

11. Since this paper was written, fourteen additional patients of this series have been treated with approximately the same results as recorded above.

estimates that there was at least 75 per cent relief. The evidence for the mold etiology in this patient, who is typical of many others, may be summed up as follows: the history of the early "season" without the corresponding pollen reactions; the positive skin tests to fungi; the clinical observation of increased symptoms during the time when the air was heavily contaminated with spores but practically free from pollen; systemic reactions from injections of mold extracts; the satisfactory results following desensitization to these fungi.

## SUMMARY

1. The ever present spores of fungi in the air are common causes of respiratory allergy.
2. A great tendency exists for many of the mold-sensitive patients to assume a seasonal character in their symptomatology because of the greater prevalence of mold spores in the warm months.
3. The evidence for the etiologic factor of molds in the group discussed consists of positive skin and passive transfer tests, the history of a "season" which is not in entire conformity with the pollen reactions, the clinical observation of the patients and comparison of their symptoms with reference to daily pollen and mold counts, the failures in pollen treatment, and the good results and a few systemic reactions with mold desensitization.
4. This group constitutes such a definite unit that with some experience most of these patients can be catalogued before sensitization tests are made.
5. Of twenty-eight patients treated by specific mold desensitization and observed during at least one season, twenty-three obtained satisfactory results.
6. The conclusion cannot be escaped that seasonal hay fever and asthma due to molds is a definite and important allergic entity, second in importance only to pollen disease.

185 North Wabash Avenue.

## ABSTRACT OF DISCUSSION

DR. HENRY C. SWEANY, Chicago: Did you ever observe any of your patients leave the environment of some particular mold and become cured spontaneously?

DR. GEORGE R. HERMANN, Galveston, Texas: Similar studies have been carried out in Galveston by Prince, Selle and others working along these lines. They have observed that there was a difference in the mold content in the atmosphere in connection with variations of the winds. With the drop of the tide and the lowered water level in the swamps about Galveston island the molds multiplied on the exposed water soaked vegetations and then dried. Then certain winds, principally from north easterly directions, whipped them off and carried them over the island and the mold count rose very high. During such times the patients who had apparently become sensitive to the mold antigen responded to the high content of mold. Skin tests were made and desensitization was carried out and reported.

DR. SAMUEL M. FLYNN, Chicago: I believe your question was whether I have noticed any of these patients leaving relief from symptoms in other parts of the country.

DR. SWEANY: Going out of the environment of the particular mold.

DR. FEINBERG: Let me explain that these studies were made in an outdoor atmosphere; these do not represent studies on particular environments of particular patients.

DR. SWEANY: What I meant was going to the Pacific Coast.

DR. FEINBERG: I have noticed some variations. For instance, I have one patient now in Tucson who is free at the present time, although she had trouble in Chicago at this time of the year. I have not made any studies of the air in Tucson. I don't know what the difference is. I suspect that there is a difference.

## GIANT CELL BONE TUMOR

## FURTHER OBSERVATIONS ON TREATMENT

CARLETON B. PEIRCE, M.D.

AND

ISADORE LAMPE, M.D.

ANN ARBOR, MICH.

In previous papers, one of us<sup>1</sup> has presented the experience at the University Hospital with giant cell bone tumor during the period from 1923 to 1931. To codify further that experience as a guide in the management of this lesion, the methods used and the results accomplished have been surveyed again in the same group of patients and in an additional number under observation in the department of roentgenology since that time.

The current series reported includes eighteen of the previous group and twenty-two additional cases, a total of forty. Although errors in diagnosis of giant cell bone tumor may be made from the roentgenographic examination, in the large majority of cases the film evidence should be sufficient for diagnosis. In twenty-five of these, biopsy or a surgical specimen has afforded

TABLE 1.—Untreated Cases

	Age of Case	Location of Tumor	Reason for No Treatment	Biopsy or Surgical Specimen	Subsequent History
1	14	Intertrochanteric area of femur	Treatment refused by parents	+	Subsequent increase in size of tumor; irradiation and surgical treatment elsewhere; microscopic confirmation of diagnosis; no later report
2	49	Seventh rib	Incidental finding; no symptoms	0	No report
3	29	Ilium, posterior inferior spine	No symptoms	0	No subsequent visit
4	14	Femur, subtrochanteric	Treatment refused by parent	0	Progressive increase in size 24 months later; treatment again refused
5	3	Humerus; proximal metaphysis	Treatment refused by parent	0	No report

microscopic proof of the roentgen diagnosis. The other sixteen are typical in roentgenographic appearance and are in accord with those proved by histologic examination.

## METHODS OF TREATMENT

Since the advent of roentgen therapy, some controversy has prevailed between the proponents of surgery and those in favor of irradiation. Others believe that a combination of the two is to be preferred. Surgical attack with chemical cauterization has been utilized with considerable success. Extirpation of the involved area by resection or excision has been advocated.

It will be observed in the tabulated cases (tables 1 to 5 inclusive) that the method of management in our clinic has varied in the same degree as is suggested severally by the articles in the literature. A general

grouping, however, can be made into (1) untreated or those treated (2) by surgical methods plus pre-operative and postoperative irradiation, (3) by surgery and postoperative irradiation, (4) by surgery only and (5) by irradiation only.

## TREATED CASES

In any evaluation of the result of treatment, several factors relative to the condition at the time of origin of treatment must be carefully weighed; namely, the extent of the lesion, the location in an essential skeletal

TABLE 2.—*Preoperative Irradiation, Surgery, Postoperative Irradiation*

Case	Age	Location of Tumor	Preoperative Irradiation	Character of Surgical Attack	Biopsy or Surgical Specimen	Postoperative Irradiation	Result	Time Interval at Last Report Since Origin of Treatment
6	34	Femur, distal	125 roentgens 2 weeks	Curettage and acriflavine	+	Multiple small doses	Clinically well	3 years
7	36	Ulna, distal	200 roentgens aa 2 ports, 1 mo.	Curettage only	+	Multiple small doses 75-125 roentgens aa 2 ports monthly for 16 mo.	Excision for increase in size at 12 mos.; good function, no recurrence at 8 yrs.	8 years
8	21	Fibula, proximal	Single small dose 125 roentgens aa anterior + posterior, 1 mo.	Excision 4 mos.	+	Multiple small doses 100 roentgens 1 mo. 100 roentgens 3 mo.	No recurrence (now under treatment for pulmonary tuberculosis)	5½ years
9	22	Tibia, head	150 roentgens aa 3 ports, 1 mo.; 150 roentgens, 1 port, 1 week	Curettage and bone chips (lysis of chips and recurrence of tumor at 4 mos.)	+	Multiple large doses 1,850 roentgens in 3 weeks beginning 9 mos.	Amputation 2 years later	3 years
10	24	Femur, intertrochanteric	350 roentgens aa 2 ports, 1 week	Saucerization, bone graft and bone chips	+	Periodic large doses 2 x 400 roentgens monthly for 4 mos. beginning 1 mo.	Persistent cystic areas; good function	9 mos.
11	17	Tenth rib (malignant change)	4 x 150 roentgens, 1 port	Excision	+	.....	Postoperative cardiac death	
12	15	Tibia, proximal (secondarily infected with inguinal adenopathy on admission)	800 roentgens aa 4 ports, 1 mo.	Saucerization	+	600 roentgens aa 4 ports at 2½ mos., 400 roentgens aa 4 ports at 6½ mos.	Flexion deformity of knee; equinus position of foot; subcutaneous fibrosis	3 years
13	33	Tibia, proximal	Periodic, large, 400-600 roentgens aa 4 ports, monthly for 4 mos.	Excision elsewhere (microscopic diagnosis of giant cell tumor)	+	No report	No report	9 mos.

TABLE 3.—*Surgery and Postoperative Irradiation*

Case	Age	Location of Tumor	Character of Surgical Attack	Biopsy or Surgical Specimen	Irradiation	Result	Time Interval at Last Report Since Origin of Treatment
14	11	Humerus, proximal metaphysis	Curettage only	+	Single large dose, 500 aa 3 ports	Excellent with bone repair; function good	4½ years
15	15	Humerus, distal	Curettage and bone chips	+	Periodic large doses, 400-500 roentgens aa 2 ports x 7, bi-monthly	Early resorption of bone chips; later increase in size of tumor; excision at 22 months	22 months
16	11	Femur, intertrochanteric	Curettage and acriflavine	+	Multiple small doses	Clinically well	3 years
17	4	Ulna, distal metaphysis	Curettage and acriflavine	+	(Multiple small) treatment elsewhere	Clinically well; anatomic repair	11 months
18	15	Ulna, distal metaphysis	Curettage and phenol	+	Multiple small doses	Clinically well	23 months
19	27	Thoracic vertebra II	Laminectomy	+	Treated elsewhere; multiple small doses	No disability; returned to work	3 years
20	25	Thoracic vertebra XII	Laminectomy	+	Periodic large doses, 600 roentgens aa 2 ports x 2 three month intervals	Partial residual palsy due to permanent damage to cord before admission; no increase in size; recalcification; good functional result	3 years
21	38	Humerus, proximal ½	Operation elsewhere twice; apparent ultimate resection, secondary infection	+	X-ray saturation series elsewhere	Gross defect in humerus; no apparent tumor; disability	21 months
22	42	Tibial head	Operation elsewhere; secondary infection	+	X-ray and radium elsewhere; data not obtainable	Persistent tumor with osteomyelitis; gross defect in skin	3 years

## UNTREATED CASES

In the entire series of forty patients, five were not treated for the giant cell tumors found (table 1). The parents of three of these refused treatment of any type, one later permitting the child to be treated by surgery and irradiation elsewhere as the symptoms increased. Two cases presented the tumor as an incidental finding without symptoms.

part or weight bearing area, the character of previous treatment not subject to the observer's control, or secondary infection. Without fairly complete information on these items an attempt to evaluate results will be fruitless, regardless of the number of cases in the series.

The number of individuals in each group of this series is small; hence percentage values are not

markedly significant. The major criteria must be the effect on the lesion in the nature of cessation of further growth, degree of bone repair, impairment or improvement of function and either ultimate retention of the affected part with safety or its excision.

TABLE 4.—Surgical Treatment Only

Case	Age	Location of Tumor	Character of Surgical Attack	Biopsy or Surgical Specimen	Result	Time Interval at Last Report Since Origin of Treatment
23	18	Fibula, head	Excision	+	No report after discharge	Clinically well 1 month
24	7	Femur, intertrochanteric	Curettage and bone chips	+	Persistent cystic areas; minimal improvement; no disability	3 years
25	18	Femur, intertrochanteric	Curettage and bone chips	+	Persistent cystic areas; good functional result	2 years
26	14	Femur, distal metaphysis	Curettage, electrocautery, bone chips and graft	+	Persistent cystic areas; apparent repair in other areas	26 months

In this series we shall speak of "excision" as the removal of the affected part of the bone *en masse*, "curettage" or "saucerization" as the removal of the

tion therapy "multiple small treatments" commonly means from 75 to 125 roentgens through several ports repeatedly over a certain length of time; "periodic large doses" means from 300 to 600 roentgens through several ports repeated at longer intervals, the x-radiation being generated at 140 or 200 kilovolt peak.

*Surgery with Preoperative and Postoperative Irradiation* (table 2).—Eight cases were subjected to preoperative irradiation. In but one of these can the preoperative irradiation be considered to have had an opportunity to become effective before surgical intervention.

Of the group only one (case 6) may be considered to have a satisfactory result. The preoperative irradiation was minimal and was given but two weeks before curettage and chemical cauterization. Patient 10, with an intertrochanteric involvement of the femur, received preoperative irradiation only one week before saucerization. This cannot be considered a marked factor in the result. Both patients received methodical postoperative irradiation, one with multiple small doses, one with periodic large doses. The functional result in both has been good.

Patient 12 had been secondarily infected and presented inguinal adenopathy on admission. In this case large periodic irradiation (malignant change suspected) has contributed, we believe, to scar tissue contraction

TABLE 5.—Treatment with X-Rays Only

Case	Age	Location of Tumor	Character of Radiation Therapy	Biopsy or Surgical Specimen	Result	Interval of Last Report Since Origin of Treatment
Multiple Small Doses						
27	8	Femur, intertrochanteric	Multiple small doses.....	0	Improved calcification; no disability; no growth of tumor	11 months
28	37	Radius, distal	Multiple small doses.....	0	Clinically well; ossification of tumor	3 years
29	21	Radius, distal	Multiple small doses (75-125 roentgens biweekly to bimonthly over a long period)	0	Clinically well; ossification of tumor	5 years
30	18	Thoracic vertebra XII	Multiple small doses.....	+	Clinically well; ossification of tumor	8 years
31	16	Fibula, head	Multiple small doses.....	0	Clinically well; ossification of tumor	11 years
Periodic Large Doses						
32	4	Humerus proximal metaphysis	200-250 roentgens $\bar{a}\bar{a}$ 3 ports monthly to bimonthly $\times 7$	0	Progressive ossification; no disability; clinically well	2 years
33	7	Humerus proximal metaphysis	350 roentgens $\bar{a}\bar{a}$ 3 ports bimonthly $\times 3$	0	Progressive ossification; clinically well	12 months
34	11	Femur, intertrochanteric	350-500 roentgens $\bar{a}\bar{a}$ 3 ports bimonthly $\times 3$	0	Increased calcification, loss of pain and limp; clinically well	7 months
35	18	Femur, distal	500-600 roentgens $\bar{a}\bar{a}$ 4 ports bimonthly $\times 4$	0	Ossification in tumor; loss of pain; peroneal palsy	20 months
36	31	Femur, distal	400-500 roentgens $\bar{a}\bar{a}$ 4 ports 1-3 months intervals $\times 4$	0	No change in tumor; recurrence of pain last visit	3 years
37	44	Thoracic vertebra X	500 roentgens $\bar{a}\bar{a}$ 2 ports monthly for 4 months	0	Moderate ossification; loss of symptoms; clinically well	17 months
38	13	Lumbar vertebra V	650 roentgens $\bar{a}\bar{a}$ 3 ports monthly for 4 months	0	Progressive ossification; loss of symptoms; clinically well	22 months
39	33	Tibia, head	400-600 roentgens $\bar{a}\bar{a}$ 4 ports bimonthly $\times 4$	+	Excision elsewhere 6 weeks after last dose	9 months
Palliative Treatment

41	45	Iscium and ilium	3 $\times$ 150 roentgens $\bar{a}\bar{a}$ anterior and posterior right pelvis; 4 $\times$ 75 roentgens chest (metastasis)	+	Relief of pain in pelvis; death 8 months later	

affected portion of the bone by a curet or similar instrument, the unaffected shell being left. In general, "excision" is to be regarded as unfavorable, in that it removes a portion of the supportive framework of an extremity and is used relatively as a means of last resort to eradicate the tumor. We admit that excision may be the method of choice in certain cases but do not feel that it is necessary in the majority. In radi-

ation therapy, which, coupled with the osteomyelitis present on admission, has not permitted a satisfactory result.

The other five have resulted in excision or amputation, one showing malignant change (case 11).

In this group, therefore, the methods of management have varied widely, and the results cannot be considered to favor either irradiation or surgery.

*Surgery and Postoperative Irradiation* (table 3).—The nine cases in this group include two patients who had been operated on and subjected elsewhere to irradiation with x-rays or irradiation with x-rays and radium. One of these patients no longer has a tumor but has lost the proximal third of the humerus with a resultant flail shoulder. The other patient still has some tumor in the tibia with secondary infection. They

excision. This was a patient of low mental development in whom excision of the fibular head was considered the method of choice. The other three have shown a good result with curettage and bone chips, or with curettage and electrocauterization followed by bone chips and graft. All three show persistent cystic areas in the operative field. The functional result has been good.

Total.....	41	21	15	1	4

*X-Irradiation Only* (table 5).—The group that received irradiation includes only fifteen cases. From this total two patients must be deleted, one to whom radiation was given only as a palliative measure for relief of pain and in whom the ischial tumor showed malignant change after having been present for fourteen years (case 40), and the second for lack of further information (case 39).

Patient 13 was subjected to an excision elsewhere, six weeks after the last irradiation. The reason for this surgical intervention is unknown.

The remaining twelve have shown good results with loss of symptoms, cessation of growth of the tumor, and recalcification in the tumor area. One (patient 36) complained of recurrence of pain at the last visit without x-ray evidence of change in the tumor. Another (patient 35) has some subcutaneous fibrosis in the popliteal area and a peroneal palsy. The contributory effect of the larger doses of radiation as a factor in the production of fibrosis in the deeper connective tissues in this case may be questioned in view of the fact that the postirradiation skin changes are minimal.

We may then consider that ten of the twelve subjected to radiation treatment only have shown good results (83.3 per cent of the immediate group).

It is of interest that half of these ten have received multiple small doses of from 75 to 125 roentgens frequently over a period of time, and the other half periodic large doses at less frequent intervals. In a comparable elapsed time, no significant variation in response has been observed. Under both methods the symptoms have disappeared, growth of the tumor has ceased, and moderate ossification within the tumor has ensued. On the other hand, the two patients in this group who have shown unfavorable results had received

have not been subjected to irradiation in this department. They may be considered as unfortunate examples of the result of multiple modes of attack and of the effect of secondary infection. A third (case 15) showed an early resorption of bone chips introduced at the time of curettage and later a recurrence in activity and growth of the tumor while still under roentgen therapy, requiring subsequent excision.

The remaining six are regarded as showing good to excellent results. (These constitute, in analysis, 86 per cent of their group, since the first two discussed should not be included in an evaluation of this method of treatment.)

Five of the patients are clinically well from eleven months to four and one-half years since the origin of treatment. The sixth patient (20) had considerable cord damage on admission, and some residuum must be expected. The functional and symptomatic result is good.

Four of these six patients received multiple small doses (from 75 to 125 roentgens, biweekly or bimonthly) over a considerable length of time, one a single large treatment (500 roentgens each through three ports), and the sixth periodic large amounts (600 roentgens each through two ports at two three-month intervals). It should further be observed that in three of these favorable cases a chemical cauterant was employed by the surgeon in addition to the curettage of the evident tumor area.

*Surgery Only* (table 4).—One of the four patients who received surgery only was subjected to a primary

TABLE 7.—Summary (Corrected for Extranous Factors)

Method of Treatment	Total Number of Cases	Results		Discarded, Because of Extranous Factors
		Satisfactory	Unsatisfactory	
Surgery with preoperative and postoperative irradiation.....	8 (7)	2 (40%)	3 (60%)	3
Surgery with postoperative irradiation.....	9 (7)	6 (85%)	1 (15%)	2

periodic large doses of radiation. These may represent the normal morbidity rather than demonstrate a specific character of response.

Logically, therefore, we cannot hold a particular brief for either method of irradiation. It is our opinion that the initial reaction of apparent lysis is more marked in the patients subjected to the larger doses. Further, the experience with one patient suggests the inadvisability of large doses of radiation because of possible damage to the deeper connective tissue.

COMMENT

A recapitulation of the results obtained by these several methods, which reflects in a measure the general lack of uniformity in treatment of giant cell bone tumors, is shown in table 6.

However, with the several cases deleted for the causes discussed in each of these groups, the distribution shifts somewhat as indicated in table 7.

With such an analysis it is evident that with thorough curettage, surgery alone is effective in the control of this tumorous lesion of bone. Contrary to our previously expressed belief, adequate curettage with or without cauterization has been as effective as curettage with irradiation.

There are those cases in which the location of the tumor, the age or physical condition of the patient, or the loss of occupational time incident on surgical attack are real factors in the life of the patient. In these, irradiation offers symptomatic relief and anatomic improvement.

Further, irradiation alone offers as much for the control or cure of giant cell tumor as either of the other methods. The comparison of surgery alone as of 100 per cent is a fallacy in so small a group of cases.

As to the method of irradiation, our immediate tabulation suggests little choice. The character of the response of giant cell tumor to irradiation continues to substantiate the belief that the growth restraint induced is specific for the giant cell, and that giant cell tumor is essentially not a true neoplasm. Hence large or massive doses are theoretically of less value than smaller and more frequent amounts of radiation and may tend to be more irritating to the normal connective tissue elements.

Cessation of increase in size of lesion and disappearance of symptoms should be considered as an indication of favorable response, although reparative changes in the involved bone are not apparent for some time

CONCLUSION

1. Lack of uniformity in the treatment of giant cell tumor by combined surgical and radiation methods defeats any attempt at satisfactory comparative analysis.
2. Preoperative irradiation has been permitted little opportunity for effect and has been urged on the radiologist largely in those cases which are unfavorable at the outset.
3. Secondary infection subsequent to primary surgical intervention or biopsy offers definite obstruction to improvement by irradiation.
4. Adequate curettage has induced good functional results in anatomically accessible areas.
5. Either adequate treatment with x-rays or adequate surgical intervention offers as much as a combination of the two.
6. Conservative treatment with x-rays will afford symptomatic relief and induce anatomic repair.

"Acid and Alkali Forming Foods."—The scientific evidence indicates, therefore, that the question of acid and alkali forming foods is a negligible problem in human dietetics. "It is still an open question," wrote Sherman (in 1932), "whether the acid base balance of the mineral elements of the diet is or is not of practical significance in human nutrition." Evidence showing the relative unimportance of the effects of acid ash and alkaline ash foods has been ably summarized in the Report of the Committee on Nutritional Problems of the American Public Health Association for 1935-1936. —Tobey, J. A.: The Question of Acid and Alkali Forming Foods, *Am. J. Pub. Health* 26:1113 (Nov.) 1936.

MULTIPLE POLYPOSIS OF COLON

FAMILIAL FACTOR AND MALIGNANT TENDENCY

DESCUM C. MCKENNEY, M.D.

BUFFALO

Multiple polyposis in recent years has been recognized as a distinct disease. This, together with the growing knowledge of the hereditary factor and high percentage of deaths from malignant degeneration, has been responsible for general interest in its study.

After diagnosing a case of multiple polyposis I have undertaken to locate and examine all the members of that family group in an effort to determine how many of them were similarly afflicted. This paper represents the result. It is not, however, intended as an exhaustive review of the subject.

Multiple polyposis, or adenomas, of the colon can, following the classification of Erdmann and Morris,<sup>1</sup> well be divided into two classes: the first, the acquired or adult type, the result of some form of irritation, and the second, the adolescent (congenital, disseminated type) characterized by familial tendency and probably in some cases at least, congenital.

Fig. 1.—Comparative size of adenomas in four children of one family, aged 2, 5, 9 and 11. As there is an average difference of two and three-fourths years in the ages and so nearly a like amount of growth for each period, it suggests congenital origin in the 2 year old and hence in all.

The acquired type is found when there is chronic irritation. Such polypi formed from the loosened edges of ulcers are often seen as a late stage of ulcerative colitis, hyperplastic tuberculosis and stricture.

Polypi of this type are irregular in size and shape, are scattered, and are few in number as compared with the other type. The diagnosis of the irritation that preceded them and the fact that they occur later in life differentiate this class from the adolescent type.

Only the adolescent type is being considered in this paper. It is observed in infancy and early life and may involve members of several generations of the same family. The distribution of the polypi is throughout the entire colon, and they may displace the normal mucosa. There is a history of frequent bowel movements, from two to six a day, often for a number of years without any apparent ill effect, but sooner or later there is blood and mucus in the stools with increased frequency and abdominal pains, due to an exaggeration of the disease itself or to a superimposed malignant condition.

Both types predispose to malignant degeneration, the incidence varying from 40 per cent upward. In my series it is 33⅓ per cent (table 5).

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

## DIAGNOSIS

By means of a digital examination it is possible to gain the first impression that the case is one of multiple polyposis. As the adenomas usually appear first in the pelvic colon and rectum, they can readily be seen through the sigmoidoscope. With the more general use of this instrument and x-rays the diagnosis of such cases has become more common, whereas previously

Fig. 2 (J. C., group A, aged 21).—Characteristic mottling due to adenomas protruding into lumen and preventing uniform distribution of the opaque clysm.

discovery was made only at autopsy or on excision of a portion of the colon for some other condition.

Despite the diagnosis of polyposis with the sigmoidoscope and x-rays, as routine procedures of the careful diagnostician, still many such cases are treated as colitis and most are diagnosed only after the appearance of the more urgent symptoms consequent on malignant change.

If a case of polyposis or polyposis with malignant change is discovered, early examination of other members of the family group may locate additional cases before serious symptoms arise.

Immature adenomas, in the form of tiny spots, 1 cm. in diameter and just ready to break through the apparently normal mucosa, can usually be found between the visible polypi. (In L. B. in figure 1 an immature adenoma is shown as a light spot near the bottom and slightly to the right.) This condition exists chiefly in those under 16 years of age. These are described by Fansler as "simply a little bulge of the mucosa as though there were a foreign body lying under it." Such forms must be searched for in infants and younger children, for only in this way is it possible to make an early diagnosis. My experience is that, with a clean mucosa and a light at the distal end of the sigmoidoscope, it is possible to focus it so as to throw its rays across the mucosa and thereby bring into relief these very small forms. The magnifying lens attachment for the sigmoidoscope may be helpful but is rarely needed. All suspicious polypi should be removed for pathologic study.

The x-rays are necessary for making a diagnosis of polypi higher than the limits of sigmoidoscopic inspection. For this condition, double contrast mediums, a barium sulfate enema, followed after its expulsion by air inflation, unmistakably constitute the most efficient method for demonstration of adenomas. Although polypi are usually most abundant in the lower part of the bowel, the roentgenogram would seem to indicate, in some cases at least, that the greatest number are in the proximal portion of the colon. A roentgenogram should be made in every case because of the possibility of carcinoma.

This study was further prompted by the hope that, with earlier diagnoses, some treatment might be found, before malignant change took place, to save some of these unfortunates from an early death.

## GROUP STUDY

With the familial tendency in mind, five cases presenting polyposis were selected for group study but in only two was it possible to get in contact with relatives in sufficient number to warrant a report. Some subjects who may be afflicted refused examination; others, examined early in the period of study, which began in 1930, may since have developed the disease, so that the figures I am to present may fall short of the actual number. Some were afraid to have an examination, stating that if they had the disease and knew it they would have that much more to worry about. They defended their stand by referring to some of their relatives who died even after a diagnosis had been made. Another argument against examination was that they did not want their children to bear the stigma that would result from their companions knowing of their affliction.

Fig. 3.—The same colon seen in figure 2; adenomas cecum to anus. Malignant degeneration of adenoma near splenic flexure was cause of death. Note absence of adenomas in pelvic colon and rectum, removed through the sigmoidoscope in preparation for colectomy.

## GROUP A

In the first group, which I shall henceforth speak of as group A, all were Italians; some spoke no English and were suspicious of the motive behind my desire to make an examination, so refused it. This group lived within 50 miles of Buffalo, some in Canada and the rest in the United States, but, on account of the depression and unemployment, few had the means to come

or examination; neither could they afford to pay for hospitalization. Some of them, however, were most cooperative and helpful in getting the others in for examination.

Individuals and hospital records were examined and in one case a history was obtained from relatives. In this way three generations were covered.

The father of a family of six children, who came to America, died at the age of 47 in Italy of "bowel trouble." His children said he had continuous loose stools preceding death, pointing strongly toward polyposis, carcinoma or both. He alone represented the first generation. His children represented the second generation of the group (table 1).

The first seen in group A was J. C., one of the six children, a woman, aged 21, who had multiple polyposis and died of a carcinoma near the splenic flexure. With this one as a nucleus the study of the group began. Three others in this family of six had polyposis. One, a brother, dying with rectal carcinoma, a sister probably with carcinoma and the third, a brother, is still alive. A sister died at 30 of rectal carcinoma, and one is still alive, free of the disease.

There were eight children in the third generation, two of whom have multiple polyposis.

Of fifteen persons in group A, I examined thirteen. The hospital records of another, who had died, were

# GROUP B

The second family group, which I shall refer to as group B, were English speaking, representing three generations. They lived from 80 to 300 miles from Buffalo, in widely scattered areas on farms and in villages, and, like the previous group, practically all were indigent, so that it was necessary to drive hundreds of miles to search for them. It took about two years, much correspondence and solicitation by friends

Fig. 4.—Section of the colon seen in figure 3. The polypi are from 3 to 5 cm. in diameter with pedicles up to 3 cm. in length.

and other relatives in order to make the contacts. When found, it took time and often repeated trips to persuade some of them to consent to an examination. The first examinations had to be made, usually, without the slightest preparation of the persons to be examined, in their homes and always under most unsatisfactory conditions. Often subsequent examinations, as necessary, revealed polyposis where lack of preparation was responsible for failure previously.

Histories of any value, except in a few cases, were unobtainable, as parents of some of the children were dead or uninterested, and some of the children were being cared for by a welfare organization or by relatives who were scarcely able to care for themselves.

None, with two exceptions, could even afford to come to Buffalo for examination, and none could pay for hospitalization, so it was necessary to go for them and return them to their homes when through with them.

It took two years to locate twenty-eight members of this group. I examined twenty-five. Hospital records of three were studied and two of these had polyposis and carcinoma, while the third had one or both diseases.

A man, representing the first generation, died of polyposis and carcinoma of the rectum (table 3).

His seven children, three of whom are dead, represented the second generation. One of these three, M. B., a woman, the first seen in this group, had polyposis and died of carcinoma of the rectum forty-one days later, at the age of 29. Another, a woman, E. J. H., died of polyposis and carcinoma at the age of 21. A male died of "bowel trouble" suggestive of the two diseases.

In the third generation of twenty children, six have polyposis. At the time of their examination the other fourteen were free of the disease.

Nine members of group B, aged 2, 5, 9, 11, 11, 13, 21, 29 and 44, five males and four females, had polyposis. A tenth in all probability had it. Three of the members with polyposis, aged 21, 29 and 44, died of rectal carcinoma and six are still alive (tables 3 and 4).

Of the forty-three persons composing the two groups fifteen, or 37.7 per cent, had polyposis; five of these,

studied and a history of another was obtained from relatives. Six of the group, aged 10, 16, 20, 21, 38 and 42, four males and two females, had polyposis. Two of them died of rectal carcinoma at the ages of 24 and 44 and a third died with all the symptoms of carcinoma, while three, aged 10, 16 and 20, are still alive (table 1).

or 33⅓ per cent, have died of carcinoma. Two were males and three females. There are two, not included in these figures, who died of "bowel trouble" and a third of rectal carcinoma. If these three could be properly assigned, there is little doubt that the percentage of both the polyposis cases and deaths in cases of polyposis from carcinoma would be raised (table 5).

Fig. 5 (A. E., boy, aged 11, fig. 1, table 3).—Mottling of multiple polyposis.

The frequency of occurrence of multiple polyposis of the adolescent type, among the residents of a community, cannot be estimated with any degree of accuracy.

The number known at any one time could be increased if, when carcinoma of the colon is diagnosed, a careful study with the sigmoidoscope and the x-rays should be made for associated adenomas, both above and below the growth. If the case should prove to be one of polyposis, an exhaustive search of the relatives would no doubt reveal many more such cases and a reexamination every five years would add new cases, while other members would have died of carcinoma in the meantime.

Doering, as quoted by Dukes,<sup>2</sup> in a review of forty cases in his tabulation of ages proves that the disease is not congenital.

The age incidence in my study of fifteen cases is shown in table 7.

The youngest patient in my series is 2 years of age. He has two sisters aged 5 and 9 and a brother aged 11. A study of the adenomas in these four children, whose ages average two and three-fourths years apart, shows so nearly a similar amount of growth for each period that, in order for the adenomas to attain the size found in the 2 year old child, in my opinion they must have been present at birth and hence congenital. The same reasoning would apply in placing the three older children in the congenital class. In order, however, to prove conclusively that the disease is congenital, an examination would have to be made at birth. The artist

has made very faithful reproductions illustrating the sigmoidoscopic pictures of the adenomas in these four children (fig. 1).

The mother, M. B., of the four children just mentioned, all of whom had polyposis, was married twice, having two children by each husband. There was no history of the disease in either of her husbands or their families.

In my series of fifteen polyposis cases there were nine males and six females, a ratio of 3 to 2. Tables 1 and 3 illustrate well the hereditary or familial factor. There seems to be no fixed rule as to the transmission from one sex to the other.

TREATMENT

After I found the cases of polyposis, some asked what I was going to do about it. At once I realized that I had brought on myself a great responsibility. The problem was not easy to solve for several reasons. One was the difficulty of caring for people living so far from Buffalo and who were unable to pay for transportation or hospitalization even after they got there. The welfare organization refused to help, because many of the afflicted were apparently not ill and because they were being moved out of their own locality. Some refused surgical or any other form of treatment. As six of the patients with polyposis were 11 years of age or under, the question arose as to the advisability of doing surgery, necessarily radical.

In selected cases, because of the malignant tendency of polyposis, the best treatment is, without doubt, surgical, such as an ileostomy followed by excision of the whole colon, or the anastomosis of the distal end of the ileum into the lower pelvic colon at a point below which the polypi have been completely removed by fulguration (fig. 3). The colon, from the cecum to the point of anastomosis, is then excised.

The difficulty of deciding whether a part or all of the colon is involved and just how much to remove, together with the technical difficulties of the operation, the uncertainty of complete removal and the dangers to the patient make a less radical procedure desirable, but, unfortunately, a satisfactory one has not been found.

2. Dukes, Cuthbert: Cancer Rev. 5: 241 (April) 1930.

Some success has been reported from the use of roentgen rays.<sup>3</sup> This treatment was also suggested by some features of success attained with it in one of my patients (A. K.) in whom the adenomas for 10 inches up were so close together that there was almost no normal mucosa visible. Roentgenograms showed the whole colon to be involved. He received two courses

of treatments, totaling 5,500 roentgens. The adenomas turned dark red and black and disappeared. Later the patient died of an infected wound following an operation by a local surgeon for carcinoma, which was not found. One can only conjecture what might have been the result had no surgery been done.

Of the fifteen patients with polyposis, six are now dead. Two of them, A. C. H. and E. J. H., died of carcinoma of the rectum before my study began. One, M. B., died of carcinoma of the rectum forty-one days after diagnosis. S. F. died of carcinoma of the rectum, and F. M. died with the symptoms of carcinoma. Another, J. C., died of carcinoma of the splenic flexure.

Irradiation was employed for palliation in only three of the six patients who were very ill (S. F., F. M. and J. C.). The latter case (J. C., group A) was one of special interest:

A woman, aged 21, seen Oct. 30, 1930, had had abdominal cramps since the birth of her 6 year old child and for three months hourly stools with bloody mucus.

Many adenomas were seen in the rectum and pelvic colon and, by x-ray examination, throughout the colon (fig. 2). During

the latter part of 1930, through the sigmoidoscope, from the lower portion of the pelvic colon and the rectum most of the adenomas were removed, preparatory to doing a colectomy (fig. 3). Their removal caused a marked decrease in the number of bowel movements, and the bleeding stopped. In January 1931 she became pregnant with the birth, in October, of a child who is still living. During pregnancy the bowel movements increased, with more blood and mucus, and she became very anemic. She would countenance no treatment that might interrupt pregnancy and, because of her two small children, refused to submit to surgery.

From April 1932 to March 1933 she was given a total of 4,400 roentgens in divided doses. Following this, what few polypi were left in the lower portion of the pelvic colon and rectum disappeared. In the summer of 1932 it was very evident, however, that a malignant condition had developed and, with gradual emaciation, she died March 23, 1933, aged 24.

Autopsy revealed the liver studded and filled with metastatic nodules. The mucosa of the colon, especially the distal half, excepting the lower pelvic colon and rectum where they had been removed, exhibited many polypi, from 3 to 5 cm. in diameter with pedicles up to 3 cm. in length (figs. 3 and 4). Clinically carcinoma had been diagnosed but the initial lesion was not located until, after death, the examination of many adenomas of the colon located one near the splenic flexure, 2 by 2.5 cm., which infiltrated the bowel wall and proved to be malignant.

Of the nine patients with polyposis who were still alive, radiation treatment was given to six (L. B., B. B., D. E., A. E., L. H. and N. F.), aged in order 2, 5, 9, 10, 11 and 11 years (figs. 1 and 5, A. E., and 6, L. H.). A roentgenogram was not taken of L. B. and B. B. Limitation of space will not permit giving details of treatment. Since their last treatment I have seen only

Fig. 6 (L. H., boy aged 11, table 3).—Marked mottling of multiple polyposis.

two of the children: N. F., from whom all polypi in the lower part of the pelvic colon and the rectum but three had disappeared, and these I removed by fulguration; and L. H., presenting the severest case of polyposis of all, showing a 65 per cent improvement in the number of polypi, with marked improvement in his general health.

3. Personal communications to the author: Lewellys F. Barker, M.D., Baltimore, Oct. 4, 1930; George E. Binkley, M.D., New York, Nov. 24, 1934; John M. Rehmsch and L. Henry Garland, M.D., San Francisco, March 5, 1931, and Dudley Smith, M.D., San Francisco, Feb. 12, 1931.

Efforts were made in every case to shield the ovaries and testicles, despite the fact that, on account of the hereditary tendency of the disease, the wisdom of such precautions was questioned by practically all from whom I sought an opinion.

Admitting the difficulty and the possibility of error in carrying mental pictures of what one sees through the sigmoidoscope at one time for comparison with that seen at another time, when examinations are far apart,

I have tried not to see improvement unless it was there. For that reason my impressions do not sound very optimistic.

The results of roentgen treatments, as given, under such unsatisfactory conditions can be summed up as follows: After the initial irradiation sickness had ceased, the abdominal distress was relieved and the normal consistency of the stools usually returned, the blood disappeared and the patient's general health improved. In two patients aged 26 and 10 years, the polypi disappeared almost completely; in other patients there was a lessening in number. Favorable reaction to treatment was apparently more marked in cases in which the polypi were scattered than in those in which they were segregated, although here it was difficult to recognize the change so readily. In some cases the bowel became more tubular, the lumen diminished and the wall firmer, although more normal later.

About two thirds of the children from whom I received reports, following in some instances slight radiation sickness, slept well, had good appetites, never had to miss a day's attendance at school and felt better than before their treatments. They were all apparently improved, so far at least as their immediate health was concerned, but as for a cure no claim is made; neither is recommendation made for the employment of roentgen therapy until further evaluation is made.

461 Linwood Avenue.

ABSTRACT OF DISCUSSION

DR. JOHN J. CORBETT, Detroit: An immense task has been performed by Dr. McKenney in reaching and examining these families. He has called attention in a forcible manner to the hereditary tendency. Three cases that have been observed by me are interesting, first, because of the remarkable relief given to two of them through roentgen therapy; secondly, because in all a malignant condition developed later on. The possibility of relieving some of these patients by means of roentgen therapy for a period of time, instead of by radical surgery, should be kept in mind, and a guarded prognosis should always be made, because in most of them a malignant condition eventually develops.

DR. THOMAS E. JONES, Cleveland: Two facts are pretty well established: first, that this disease does have a hereditary tendency, and, second, that if these people live a normal span of life a malignant growth will develop in all of them. The treatment heretofore has been rather heroic, total colectomy and permanent ileostomy. An ileostomy in a young per-

son is rather a distressing situation. I should like to say a word about the surgical treatment of this disease, and I believe it offers one way out of a necessary total colectomy. A patient came under my observation in 1926, when she was 28 years of age. She had been advised to have a colectomy but refused it on account of having to have a permanent ileostomy. She was cachectic and had obstructive symptoms because the colon from the anal margin to the cecum was filled with polypi. I induced her to have a cecostomy, telling her I could close that at a later time when she recovered from the obstruction. She recovered in three months, and on proctoscopic examination the polypi were only about half the size they were originally. The edema had subsided. She was bleeding, however, and in order to tamponize and to aid, I started to fulgurate the polypi. She came in every six or eight weeks, and I fulgurated fifteen or twenty polyps at a time. In 1930 I did an ileosigmoidostomy, and five months later I did the resection of the colon from just above the anastomosis around the cecum. She was alive and well four years afterward, without recurrence. In 1934 she was having one or two normal stools a day. I believe that with this method the four-year period can be cut down. A cecostomy first, for drainage, then fulguration of the polypi could possibly be completed in from four to six months, which would then also cut down the possibility of its becoming malignant before one completed the total removal of the colon from the point of anastomosis.

DR. DESCUM C. MCKENNEY, Buffalo: Of course some less radical treatment than surgery would be desirable, but unfortunately there is none available that is entirely satisfactory. In my files are a number of personal communications giving some favorable reports with the use of x-rays. My experience with such treatment is given in the latter part of the paper.

DERMOID AND EPIDERMOID TUMORS  
(CHOLESTEATOMAS) OF CENTRAL  
NERVOUS SYSTEM

J. GRAFTON LOVE, M.D.  
AND  
JAMES W. KERNOHAN, M.D.  
ROCHESTER, MINN.

This report is based on a clinical, surgical and pathologic study of fifteen congenital epithelial tumors (epidermoids, dermoids, pearly tumors and cholesteatomas) of the central nervous system that have been verified microscopically at the Mayo Clinic. Fourteen of the fifteen patients who harbored these tumors were operated on by the members of the neurosurgical staff of the clinic, with three postoperative deaths. Fourteen of the tumors were intracranial. One dermoid was found in the spinal cord.

The clinicians in the Section on Neurology of the Mayo Clinic have kindly permitted us to include the clinical observations in these cases, thus enabling us to give a complete story of this unusual and very interesting group of tumors.

LIFE HISTORY OR CLINICAL FEATURES

Pearly tumors (epidermoids and dermoids) are congenital new growths and since they arise from misplaced or aberrant epithelial tissue, the foundation for these tumors is laid early in the intra-uterine life. The evidence indicates that these tumors grow as does any other neoplasm, although the rate of increase in size is extremely slow. These tumors, because of their

Owing to lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the authors' reprints.  
From the Section on Neurologic Surgery (Dr. Love) and the Section on Pathologic Anatomy (Dr. Kernohan), the Mayo Clinic.

insidious development and because of their situation within the central nervous system, may never give rise to symptoms or signs indicative of their presence. They may be accidental and accessory observations at the time of a carefully conducted necropsy. On the other hand, these lesions may be so situated as to give rise to symptoms and signs relatively early, either as a result of encroachment on some important structure, such as the optic nerve, or as a result of interference with the normal circulation of the cerebrospinal fluid. The symptoms and signs produced by an intradural epidermoid are not characteristic of this tumor but are those of any tumor that is similar in size and situation, except possibly for the slowness of development, which is not an accurate criterion. So far as we are aware, an intradural epidermoid has never been diagnosed prior to operation or necropsy, unless it be in the second case reported by Olivecrona in his paper on suprasellar cholesteatomas. Olivecrona<sup>1</sup> operated on a girl aged 19 years for a suprasellar cholesteatoma, and a few days later a woman aged 27 was admitted to his service with exactly the same ophthalmic and roentgenographic manifestations. He felt that he was justified in venturing a diagnosis of suprasellar cholesteatoma in the latter case. At operation, the conditions found were similar to those in the first case. The extradural and intradiploic epidermoids often produce a characteristic roentgenogram, and, when they do, a diagnosis is not difficult. This diagnosis has been made many times by many different observers. As far as intraspinal epidermoid tumors are concerned, they are not diagnosed prior to operation or necropsy. They frequently are associated with more or less obvious congenital lesions, particularly of the spinal column, such as spina bifida, either manifest or occult. The presence of a congenital tumor or congenital compression of the spinal cord can be suspected, but its true nature must await exploration.

#### DIAGNOSIS

The diagnosis of an intracranial epidermoid is the diagnosis of any intracranial neoplasm, except that it possibly is slightly more difficult owing to the extreme slowness of development of the tumor. The localization in some cases is determined by ordinary neurologic methods; in others, the ocular changes (defect in the visual field) denote the situation of the growth. However, it is necessary to employ either ventriculography (if choked disks are present) or encephalography to detect and localize some of these tumors. Likewise injection of iodized oil at times is necessary to localize intraspinal congenital epithelial tumors. As stated previously, the intradiploic and extradural epidermoids usually can be diagnosed by roentgenography.

#### REPORT OF CASES

This report is based on a careful study of fifteen<sup>13a</sup> cases collected from the files of the clinic. In ten of the cases the tumors were verified microscopically as epidermoids. All these tumors were intracranial, seven being intradural and three extradural. Five tumors

were verified microscopically as dermoids; three of these were intracranial and intradural; one was intraspinal, intradural and intramedullary. The fifth tumor was extracranial but, because of the erosion of the skull and the finding of structures within the tumor which unmistakably pointed to an origin common to that of the intracranial dermoids, it has been classified as an intracranial tumor.

CASE 9.—A white woman, aged 43, registered at the clinic on April 4, 1935, because of headache and a "soft spot" in the right parietal region. At the age of 10 years she had received a blow on the right parietal region. A hematoma had formed and after it had disappeared she had noted a defect in the skull. When she was 40 years of age the defect had begun to increase in size. Six months before she came to the clinic she had struck the "soft spot" on a nail; after that the defect had increased rapidly in size, and bulging had been noticed for the first time.

The patient always had been of the nervous, high-strung type and she had been accustomed to worrying a great deal.

Examination at the clinic revealed that the skull in the right temporoparietal region had been replaced by a soft, doughy mass, about 7.5 by 5.5 cm. This mass was elevated about 1 cm.

Fig. 1.—Erosion of skull caused by epidermoid; increased density above mastoid process represents an osteoma which was a secondary finding; the metallic clip is a "bobbie pin" in the patient's hair.

above the level of the scalp. The bony defect was irregular in outline. No tenderness was present on palpation. The general physical, ophthalmic, neurologic and laboratory examinations did not reveal any abnormality except that roentgenograms of the skull revealed a sharply defined, irregular region of destruction, which involved both tables of the skull, just posterior to the coronal suture in the right parietal region. The bone was thickened about the periphery of the destruction (fig. 1). Just posterior to the right mastoid process was a dense region about 3 cm. in diameter. A clinical diagnosis of epidermoid was made.

April 23, 1935, the mass was explored and found to be a large (4 by 8 cm.) cystic tumor, which was situated extradurally and extended outward to the periosteum; the intervening bone had been completely destroyed. The tumor was removed completely; the outer layer of dura also was removed with the tumor, in order to prevent recurrence. At the same time an osteoma (see roentgenologic observations) was removed from the mastoid region. Convalescence was entirely satisfactory. It was necessary to aspirate the wound on several occasions because of the tendency for the defect to become filled with serum. The patient was dismissed from the hospital eight days following operation, at which time the wound was healed and the neurologic examination did not reveal anything abnormal.

1. Olivecrona, Herbert: Suprasellar Cholesteatomas, *Brain* 55:122-134 (March) 1932.

13a. Since this paper was presented in Kansas City one of us (Love) has successfully operated on two additional congenital epithelial tumors of the brain. One of the patients presented more or less classic symptoms and signs for a Rathke pouch cyst, but when the tumor was removed and the tissue studied by Kernohan it was discovered that the tumor was a true epidermoid cyst. The other patient had had grand mal seizures for sixteen years. His neurologic examination was negative, but encephalography disclosed a defect in the anterior horn of the right lateral ventricle. At operation a very large intracerebral dermoid cyst was removed.

The histologic picture was identical with that found in case 1 except that the wall of the cyst was slightly thicker than it was in case 1; nevertheless, the wall of the cyst was made up of squamous cells with keratohyaline granules. There were no basal cells, hair follicles, sweat glands or sebaceous glands.

Letters indicate that the patient's health is good, but she is much concerned about the defect in her skull and is suffering from cancerphobia.

In this case there seems to be a direct relationship between trauma to the skull and the subsequent development of a neoplasm at the site of injury.

**CASE 12.—History.**—A single woman, aged 30, registered at the clinic Aug. 22, 1935, complaining of diplopia, vomiting, dizzy spells and headache. In January 1935 she had noted transient attacks of diplopia, associated with occipital headaches. In March she had noted blurring of the vision, especially for close objects. About the same time vomiting, without nausea, had made its appearance. In May the patient had begun to complain of dizziness and had had difficulty with locomotion, which she had attributed to defective vision. The patient had been an "intelligent, wise-cracking young lady."

Ocular examination at the clinic did not reveal any abnormality. There was definite and rather marked rigidity of the neck; otherwise the neurologic examination did not reveal any evidence of an intracranial lesion. Roentgenograms of the head and neck disclosed benign frontal hyperostosis and a fusion of the second and third cervical vertebrae. The latter was considered to be a congenital anomaly. A tentative diagnosis of a tumor of the posterior fossa was made: ventriculography revealed a symmetrical internal hydrocephalus, which confirmed the suspicion of the presence of a lesion in the posterior fossa. A suboccipital craniectomy was performed by Dr. Adson, August 30. Incision of the dura mater in the midline revealed a brownish encapsulated tumor. The tumor was cystic and from it a semisolid brownish yellow substance was aspirated. The wall of the cyst was removed completely. The tumor was situated in the vermis and did not involve the fourth ventricle; that is, there was a "wall" of brain tissue between the tumor and the roof of the fourth ventricle. The wound

**Pathologist's Report.**—The stratum celluloseum was typical, but in addition to the basic staining material found in the previous tumors there were occasional hair shafts without definite bulbs. The tumor was lined with squamous stratified epithelium; it contained some keratohyaline granules, but no basal cells were present. There were some hair shafts, but hair follicles were not found, although the hair shafts were surrounded by epithelium. There were sebaceous glands, but no sweat glands or apocrine glands were present. Around

Fig. 3.—Semidiagrammatic representation of tumor (case 13) drawn from observations at operation and ventriculograms that were made prior to removal of epidermoid.

these epithelial structures there was a very thick wall of dense hyaline connective tissue and clefts from which cholesterol crystals had been dissolved during the histologic technical procedures. Around some of these clefts there were foreign body giant cells.

**CASE 13.**—A white man, aged 39, was referred to the clinic because of convulsive seizures, loss of memory and disturbance of mentality. At the age of 11 years a piece of steel had been extracted from his left eye and the vision in this eye had been permanently lost. He had been discharged from the army in 1918 because of "blindness." In 1925 he had received several contusions of the head when two busses had collided. In 1932 he had been knocked unconscious by a bicycle. In 1936 he had been knocked unconscious when some one had thrown a metal shoe from a second story window and struck him on the head. The history of the convulsive seizures was difficult to theorize because of the patient's faulty memory and tendency to theorize about his condition. Apparently, he had had his first convulsion in 1931. Two years later he had had another convulsion; after this the convulsions had recurred with increasing frequency. Four years (1932) prior to his registration at the clinic he had first noted diminution in the sense of smell on the right side. He gradually had lost the sense of smell entirely. He had become more and more forgetful and absent minded. He had been unable to concentrate, and mental effort had fatigued him unduly. There had been some attacks of very bad smell (sense of smell was lost objectively) which had been associated with nausea and giddiness.

Examination at the clinic revealed that the patient appeared anemic. He was very loquacious and his conversation was chiefly in technical (medical) jargon which was at times very difficult to comprehend. The value for the blood pressure was only 98 mm. of mercury for the systolic and 66 mm. for the diastolic. His basal metabolic rate was —14 per cent. The acuteness of vision was 6/30 in the left eye and 6/6 in the right eye. The pupils were equal in size; the reflexes were normal for the right eye, but those for the left eye were diminished about 50 per cent. Examination of the ocular fundi disclosed a moderate pallor of the optic disks without loss of substance, which suggested a beginning primary optic atrophy.

Fig. 2.—Healed wounds after operation for tumor of brain.

healed by first intention (fig. 2). The patient was dismissed from the hospital sixteen days, and from our care twenty-two days, following the operation. At the time of her dismissal her eyes were normal; she walked with a little unsteadiness of gait but there was no headache, diplopia, dizziness or vomiting. A letter received from the patient March 14, 1936, revealed that she was in excellent spirits at that time and was "wise-cracking" as usual; her letter was profusely illustrated with character sketches.

Examination of the fields of vision revealed an incomplete bitemporal hemianopia. Neurologic examination revealed complete loss of smell bilaterally. Hearing was reduced in each ear. The tendon reflexes were diminished and no abnormal reflexes could be obtained. Roentgenograms of the head disclosed flattening of the sella turcica, with erosion of the posterior clinoid processes. The clinical diagnosis was basofrontal tumor or suprasellar cyst with hypopituitary syndrome. A right transfrontal exploration of the basofrontal region, which was performed by one of us (Love) March 20, 1936, disclosed a very large grayish, pearly tumor. Only the distal third of the right olfactory nerve could be seen when the right frontal lobe was elevated. The tumor surrounded the remainder of this nerve, hid both optic nerves and the optic chiasm from view, and extended laterally under the temporal lobe into the middle cranial fossa (fig. 3). When the capsule of the tumor was incised, flaky, avascular material, characteristic of that seen in epidermoids, was uncovered. By means of scoop and aspirator, the entire tumor was removed, except for a small piece of capsule that was intimately associated with the circle of Willis. A fairly large chunk of tumor was removed from the left optic foramen. When the tumor had been removed, both optic nerves, the optic chiasm, the anterior portion of the circle of Willis and the interior of the sella turcica appeared much as they do after a very extensive excision of a large tumor of the pituitary body. The wound was washed thoroughly with physiologic solution of sodium chloride to remove any loose pieces of the tumor and then was closed. Two Penrose cigaret drains were inserted to facilitate further cleansing of the operative field of any of the toxic substance of the tumor. The drains were removed forty-eight hours after the operation. The convalescence was uneventful and the patient was dismissed from the hospital on the eighth postoperative day (fig. 4). Postoperative neurologic examination did not reveal any change in the patient's condition. Examination of the eyes, two weeks following removal of the tumor, was made too soon to indicate what improvement in vision might occur. The patient, however, could read well.

The tumor was a typical epidermoid very similar to that described in case 1. The patient appeared anemic. His skin was pale and his appearance suggested cachexia, although his state of nutrition was satisfactory and the results of the blood count and the value for the hemoglobin were normal, as they also were in case 3. The patient's appearance, the low value for the blood pressure, and the low basal metabolic rate suggested hypopituitarism. These observations in association with the ophthalmic and roentgenographic evidence of a lesion in the region of the sella turcica brought up the question of a lesion of the pituitary body. As so often happens, exact diagnosis was impossible until the lesion was uncovered at the time of operation.

#### **PATHOLOGY**

In the presentation of these cases we have distinguished epidermoid from dermoid cysts. We have considered those tumors in which only squamous and basal type of epithelium were present to be epidermoid tumors. Cysts containing other elements of the normal skin, such as sweat glands, sebaceous glands, hairs or hair follicles, we have designated as "dermoid cysts." There were ten intracranial epidermoids, while there were three dermoids of the brain and one of the spinal cord; there was one dermoid cyst between the skull and the scalp. It was doubtful whether this tumor should be included in the present study, but it has been included because of several unusual and interesting features. Trauma has been thought to be of considerable importance in the etiology of these tumors by allowing remnants of the epidermis to be carried into the deep layers of the scalp or even between the inner and outer tables of the skull. These remnants could thus act as

an anlage of epidermoid or dermoid tumors. In case 14 there was one fact which suggests that traumatic misplacement of the epidermis of the scalp was not a factor in the etiology of the tumor. We found apocrine glands ("skunk glands") in the wall of the cyst, and apocrine glands are not normally present in the scalp but are found only in such places as the skin of the breast, axillae, and around the anus (fig. 5). The presence of these glands in the dermoid between the scalp and the skull suggests an embryologic malformation as the anlage for this and probably for most other such dermoids and epidermoids. However, trauma may serve to draw attention to them and even may hasten the progress of such growths.

Dermoid and epidermoid tumors of the nervous system may be divided into the following subgroups: those found in the cerebellum, those found in the spinal cord,

Fig. 4.—Appearance of patient 13 following his dismissal from the hospital; right transfrontal wound well healed.

those which originate in the basotemporal region and which extend into the temporal lobe, into the suprachiasmatic region or even into the frontal lobes, and, finally, those found between the tables of the skull. There is nothing which is characteristic microscopically of any one of these tumors; all are similar.

We consider squamous epithelium that can be identified as such a necessary criterion for the microscopic diagnosis of an epidermoid tumor. We have studied several tumors the contents of which were typical of dermoid or epidermoid tumors, but when we could not identify squamous epithelium in the walls of these cysts we did not classify them as dermoids or epidermoids. Squamous epithelium has several characteristics by which it can be identified. The presence of keratohyaline granules is necessary (fig. 6). These granules are present only in squamous epithelium, and only in the superficial layers. Prickle cells or squamous cells with intracellular bridges are also characteristic, but

frequently these bridges cannot be observed. Cornification of the superficial layers is perhaps one of the most constant characteristics, and during the stage of cornification the keratohyaline granules disappear. The cornified cells are then desquamated and it is these desquamated cornified cells which constitute the contents of the cysts. On this account, cholesterol crystals are rarely found in epidermoids; this is readily proved by

Fig. 5.—Wall of cyst showing (a) sebaceous glands, (b) sweat glands and (c) apocrine glands (slightly reduced from a photomicrograph with a magnification of 75 diameters).

microscopic or chemical analysis of one of these cysts. We found cholesterol crystals in several of the tumors in the cases described, but these crystals were associated with old blood pigment, hyaline and other types of connective tissue, and lymphocytes, but not alone with the desquamated epithelium or the secretions of the sebaceous glands or sweat glands. We observed blood vessels in several of these cysts and it seemed to us that the cysts must have ruptured at some previous time and allowed the mesodermal elements to enter the cysts.

Basal cells are frequently associated with squamous epithelium, but they are not always present in epidermoid cysts; when, however, they are observed, other elements that are characteristic of skin usually are present and the tumor is a dermoid. Hair present in a dermoid tumor of the nervous system seldom has good roots or hair bulbs, although the stalks are frequently surrounded by squamous and basal epithelium which are typical of hair follicles. Occasionally, hair stalks puncture the walls of dermoid tumors and project into the surrounding brain tissue without even being surrounded by epithelium. When this phenomenon is observed, the brain tissue apparently has no resentment toward the foreign body, since there is no cellular reaction on the part of the brain tissue around the hair shaft.

The only change in the brain as the result of the tumor is one of local atrophy, which is attributable to pressure exerted by the expanding cyst. The ganglion cells disappear in the neighborhood of the tumor and there is frequently a mild degree of gliosis. Occasionally, foreign body giant cells were observed in these cysts but they were always in the cysts and surrounded cholesterol crystals which acted as foreign bodies.

In one of our cases we encountered a large number of daughter cysts within the main cyst (fig. 7). This was a unique observation. The walls of the daughter

cysts contained the same type of epithelium as did the mother cyst; therefore the daughter cysts were readily identified as epidermoid cysts. We have no explanation to offer as to how these small cysts occurred or by what process they occurred. If they had been situated outside the main cyst it would have been possible to explain them on the same basis as the mother cyst, namely, as cell rests, but it is difficult to understand how cell rests could enter the large cyst which grew after birth. The cyst in which they were encountered contained much mesodermal tissue, which probably had gained entrance through a previous rupture, and it is possible that the daughter cysts had gained entrance at the same time or in a similar way. We have already mentioned the presence of apocrine glands in the wall of one of these cysts; such glands are not generally recognized as being present in dermoid tumors, but their presence should be no surprise because of the peculiar odor noted in the contents of some dermoid cysts.

*Differential Pathology.*—It is necessary to distinguish dermoid or epidermoid tumors from several other types of tumors of the brain or spinal cord. The most common neoplasm with which epidermoids are confused or to which they bear the closest similarity are adamantinomas or cysts of Rathke's pouch.<sup>1</sup> The latter neoplasms can be and usually are diagnosed correctly by their characteristic roentgenologic appearance. On microscopic examination, adamantinomas have a characteristic stroma with numerous anlagen of teeth which are characteristic. These tumors also produce characteristic roentgenologic shadows.

Epidermoid or dermoid cysts must also be distinguished from gliomatous cysts;<sup>17</sup> but this is easy, as the latter cysts usually contain a clear yellow fluid which coagulates on standing and the walls of the cysts are not lined with epithelium but are lined with neo-

Fig. 6.—Epithelium of epidermoid cyst resting on brain tissue; the superficial cells contain typical keratohyaline granules; specimen stained with hematoxylin and eosin (slightly reduced from a photomicrograph with a magnification of 400 diameters).

plastic glial cells. Abscess of the brain does not have an epithelial lining and the contents are usually purulent matter from which diverse organisms can be obtained on culture. The clinical course of abscess of the brain is usually short and associated with fever; epidermoid tumors usually progress slowly and the

17. Craig, W. McK., and Kernohan, J. W.: *Cerebral Cysts*. J. A. M. A. 102: 5-10 (Jan. 5) 1934.

clinical course is afebrile. There is one condition to which an epidermoid tumor, or so-called cholesteatoma, is frequently likened, namely, the so-called cholesteatoma which is frequently found in the lateral ventricle of the horse. We have recently had an opportunity to study two specimens of this tumor and there is not even a remote resemblance to the epidermoid or dermoid tumor found in the human brain. The cholesteatoma

Fig. 7.—Contents of cyst, showing daughter cysts lined by squamous epithelium; cysts surrounded by inflammatory connective tissue (slightly reduced from a photomicrograph with a magnification of 110 diameters).

of the lateral ventricle of the horse is a tumor which is made up of masses of calcium embedded in connective tissue which contains some cholesterol crystals. Occasionally these crystals are surrounded by some foreign body giant cells. There is no basic staining or cornified desquamated epithelium, and the entire mass is surrounded by a thin layer of connective tissue outside of which are cells of the choroid plexus. These tumors are similar to much smaller masses normally seen in the human brain. In describing epidermoid tumors of the brain, reference is frequently made to so-called cholesteatoma of the ear. The latter condition is usually the result of a chronic infection in which the products of inflammation do not drain from the middle ear but accumulate and gradually erode the bone. There is no squamous epithelium surrounding this mass, which is made up of debris resulting from dead cells.<sup>18</sup>

The epidermoid cysts between the inner and outer tables of the skull produce a peculiar roentgenogram which may be simulated by certain sarcomas of the skull, but there is no difficulty in arriving at a differential diagnosis after examining a specimen microscopically. In the same way, epidermoid cysts are easily distinguished from osteitis fibrosa cystica. Sebaceous cysts of the scalp should be distinguished from dermoid or epidermoid tumors situated between the scalp and the skull. The greatest difference between these cysts is the absence of squamous epithelium and keratohyaline granules in the wall of the sebaceous cysts; the latter are lined with a secreting type of epithelium.

Echinococcus cysts frequently have been found in various portions of the brain and spinal cord, and epidermoid cysts must be distinguished from them. Squamous epithelial cells do not line echinococcus cysts, and the contents of the two cysts are also different. Hook<sup>1</sup>

lets can usually be found in the contents of echinococcus cysts, which are fluid in contrast to the semisolid contents of epidermoid cysts or dermoid cysts.

#### COMMENT

The average age of the patients who had dermoid tumors was 22.3 years at the onset of symptoms; the greatest age at the time of onset was 29 years. The average age of patients who had epidermoid tumors was 20 years at the time of onset; the greatest age at the time of onset was 34 years. The average duration of symptoms was sixteen years in cases in which epidermoids were present and eight and a half years in cases in which dermoids were present. The youngest patient who had a dermoid tumor was 2½ years of age, and the youngest patient who had an epidermoid tumor was 24 years of age at the time of examination at the clinic. Twelve of the fourteen patients (85.7 per cent) who had a congenital epithelial tumor (dermoid or epidermoid) in the head complained of headache. Voris, Adson and Moersch,<sup>19</sup> in a study of 314 cases in which tumors of the frontal lobe were verified at the Mayo Clinic, found that 83 per cent of the patients complained of headache; the next most frequent symptom was convulsive attacks. In our series, only two patients had had convulsions; both of these patients had tumors that were situated in the basofrontal region. It is of interest to note that 78.5 per cent of the patients in our series of cases displayed definite alterations in their mental reactions, a proportion which is higher than that (63 per cent) found by Voris, Adson and Moersch in cases in which tumors involved the frontal lobe. It is known that mental disturbance<sup>20</sup> is a frequent finding in cases of tumor of the brain, but it is difficult to account for such a high percentage in this series of tumors, most of which did not involve the frontal lobes. A congenital intracranial dermoid or epidermoid should be suspected in any case in which mental disturbance is associated with headache that has

Fig. 8.—Perimetric fields (case 13) showing bitemporal hemianopia.

been present for a long time and suggests increased intracranial pressure. This is particularly true if another congenital lesion has been detected. A high degree of suspicion may lead to an accurate preoperative diagnosis in such cases.

Five of the patients in this series had edema of the optic disks at the time they were examined at the clinic.

18. Lille, H. I., and Stark, W. B.: The Insidious, Symptomless, Destructive Effect of Cholesteatoma. *S. Clin. North America* 6: 1359-1364 (Oct.) 1926.

One had an associated defect in the field of vision which was sufficiently characteristic to localize the tumor. Three patients had visual defects, the one just mentioned and two others; one of the latter, patient 13, also had pallor of the optic disks (fig. 8). The visual defects were accurately localizing.

The presence of a tumor and its situation were correctly diagnosed preoperatively in eleven of the fourteen cases in which the tumors occurred in the head. Encephalography was employed in two of the remaining three cases. By this procedure an expanding lesion was definitely demonstrated in one case, and in the other case the roentgenograms were suggestive but inconclusive.

In eight cases the tumors were diagnosed and localized by neurologic and ophthalmic methods. In four cases the tumors were diagnosed by palpation of the head. Roentgenograms of the skull confirmed the presence of a tumor in these four cases; in two of these cases the roentgenogram was so characteristic that a correct preoperative diagnosis of the type of tumor was made. In the third of these cases, in which the tumor was the first of the type seen, the condition would be recognized now, for the roentgenograms were characteristic. In the fourth case the tumor had been diagnosed elsewhere by aspiration of the contents of the cyst.

Extradural epidermoids can usually be recognized in the roentgenograms. The characteristic appearance at first is that of a more or less smooth erosion of the calvarium and a ballooning of the tables of the skull; later, one or both of the tables may be destroyed. When the outer table is destroyed, a soft doughy mass can be palpated over a defect in the bone. Calcium may be observed in the wall of the tumor.

There are no criteria for making a correct diagnosis of the type of intradural tumor prior to operation. Intracranial tumors may produce symptoms for many years. In some of the cases in this series, symptoms had been present for as long as twenty years, but the symptoms usually are not known or considered to be the result of the tumor until after it has been discovered either at operation or at necropsy. There usually is a change in the character or severity of the symptoms or additional disturbances that lead to a careful investigation and to the discovery of an intracranial tumor.

The relationship of trauma to these tumors is not clear. Trauma to the region of such a tumor doubtless will influence its growth, but we do not feel that injury in itself is sufficient to cause the tumor. Fortunately, a preoperative diagnosis of the type of tumor is not necessary, for these tumors lend themselves admirably to surgical extirpation and the results of operation are very gratifying.

In fourteen of the fifteen cases studied, operation was performed. There were three postoperative deaths. A child, aged 2½ years, died because of increased intracranial pressure, eleven days following operation for a dermoid cyst of the cerebellum. There was no evidence of meningitis. A man, aged 30, died of bronchopneumonia five days following operation for a dermoid cyst of the right temporal lobe. No meningitis was discovered. The third death was that of a woman, aged 32, who succumbed half an hour following the complete removal of a large epidermoid from the fourth ventricle. At necropsy, no adequate explanation for her death could be found.

#### SURGICAL REMOVAL OF DERMOID AND EPIDERMOID TUMORS OF THE CENTRAL NERVOUS SYSTEM

The treatment of these tumors is surgical removal, and the surgical extirpation should be as complete as possible. One has to be satisfied at times with an intracapsular enucleation, but there certainly is a chance of recurrence if the capsule is left behind, for it is the capsular portion which constitutes the active growing portion of the tumor. Roentgen therapy is without avail, as one would naturally suppose from the life history and microscopic structure of these tumors. The intradiploic and extradural tumors offer no surgical problem, but one must be careful in removing an intradiploic tumor lest one overlook an extension of the tumor intracranially through the thinned and eroded inner table of the skull.

The surgical approach to these tumors does not differ from that of any similarly situated neoplasm. There are, however, some points of technic which are peculiarly applicable to this class of tumors. Because of the avascularity of these lesions, the exposure does not have to be as wide as does that for a glioma or meningioma of similar size. The contents of these tumors can be removed with a scoop and an aspirator, and the collapsed capsule then can be removed without encountering much bleeding. Usually, a few small vessels will have to be controlled by means of electrocoagulation. It is usually possible to effect a complete extirpation of the contents and then the capsule. However, when a portion of the capsule is intimately associated with an important structure, such as an optic nerve or a branch of the circle of Willis, one should not sacrifice such a structure in order to accomplish total removal, for these tumors grow very slowly and it is the better part of surgical judgment to risk the chance of recurrence of the tumor than to do irreparable damage in effecting complete removal of a benign tumor.

There has been a great deal written and more said regarding the development of meningitis following operations for the removal of these tumors. We have not had an instance of meningitis in this series of cases. We have seen meningismus but have never obtained any organisms from smears or cultures of the cerebrospinal fluid following operation; in the cases in which death occurred there was no evidence of meningitis at necropsy. We believe that drainage of the operative field for forty-eight hours following operation is of distinct value. This encourages a washing to the outside of any of the toxic contents of the tumor that may have been spilled at the time of operation.

#### SUMMARY

Dermoid and epidermoid tumors (cholesteatomas or pearly tumors) of the central nervous system are benign, congenital neoplasms of epithelial origin. Their clinical course is variable and the intradural variety is not diagnosed prior to operation. The extradural type can be recognized roentgenographically. Surgical removal of these tumors is possible and the results are good. A diagnosis of tumor was made in each of the fifteen cases reviewed, and fourteen of the fifteen patients were operated on and the presence of a tumor verified at operation. There were three postoperative deaths. The other patients recovered and were living at the time this paper was written; the length of life varied from one month (in case 13) to six and a half years following the surgical removal of the tumor.

## ABSTRACT OF DISCUSSION

DR. ERNEST SACHS, St. Louis: I have had six cases that fall into this group, which is a little less than 1 per cent in the tumor series. It is a rare condition in my experience. All the cases were of the epidermoid type. None corresponded to the type that the authors spoke of as the dermoid. They were all intradural tumors. It has been my experience, just as the experience in the Mayo Clinic, that prior to the operation it was possible to make a pathologic diagnosis. These tumors, in a number of instances, developed very slowly, but that would not be a point that would enable one to differentiate or predict what sort of a tumor one would encounter. Two cases are of particular interest. Of the six cases, four were located in the posterior fossa, one was around the chiasm and one was located in the incisura, lying just over the vein of Galen. The patient was operated on twice. At the first operation I thought I was dealing with a posterior fossa tumor and tried to reach it through the posterior fossa. Subsequently by combined operation I was able to get the tumor out, capsule and all. I have had one other case that was of particular interest in bearing on the point made, namely, that it is necessary to remove all the capsule in order to obtain a cure. The patient was a girl whom I operated on in 1922. At that time a diagnosis of eighth nerve tumor was made. At operation in the region of the eighth nerve, embedded in the bone, I found a typical (at that time it was called cholesteatoma) epidermoid tumor. The notes made at that time stated that I had removed the entire tumor and the capsule. This girl came back thirteen years later with an enormous recurrence. I operated on her a second time. The tumor at this operation weighed 41 Gm. She died of bronchopneumonia several days after the operation. Evidently I had left a bit of the capsule, although I was under the impression that I had removed all of it. It is absolutely essential, in order to avoid a recurrence, to remove every bit of the capsule, if possible. One of the tumors around the chiasm, similar to the one the authors showed, I believe I have removed entirely. It is a number of years since this girl was operated on, but there too I am wondering whether one of these days the patient may not return. In these six cases, nine operations were performed. One patient died at the second operation and two others died, of a fourth ventricle tumor and one in the angle, immediately after operation. I was somewhat at a loss to explain the origin of the tumor lying in the incisura. Perhaps Dr. Bailey can explain how an epidermoid tumor can develop just above the vein of Galen, lying at the form of the incisura. I presume it is an epithelial rest which, of course, one cannot find anywhere. It seems worth mentioning such an unusual location.

DR. R. GLEN SPURLING, Louisville, Ky.: The authors have covered the subject of epidermoids in a thorough and instructive manner. In my series of approximately 200 verified brain tumors there were two cholesteatomas, one in the cerebello-pontile angle, the other in the left frontal lobe. There were no unusual features to the angle epidermoid; the frontal one, however, was associated with an extraordinary clinical history: A boy of 17 years was admitted to my service May 31, 1931, with complaints of headache, vomiting and drowsiness. The acute symptoms were of three weeks' duration, but he had been subject to headache for about a year. The past history was negative except for typhoid two years previously, from which he made an uneventful convalescence. The neurologic examination led to the diagnosis of a left frontal lobe tumor, and he was prepared for craniotomy. Before turning the frontal bone flap, I did a needle exploration of the frontal lobe through a burr hole in the hope of tapping a cyst. Much to my surprise I evacuated a large abscess, the pus from which yielded a pure culture of typhoid bacillus. The abscess refilled promptly and after several aspirations a wide exploration of the cavity was made. After the purulent material was cleared away a glistening circumscribed mass was uncovered. This mass was approximately the size of a hen's egg and had the typical appearance of a cholesteatoma. It was removed completely. The abscess wall was drawn to the surface and attached to the glia. Healing progressed satisfactorily and the patient was discharged August 11, free from symptoms. He has remained well to date. Microscopic examination of

the specimen showed the typical appearance of a cholesteatoma. What sequence of events led to the formation of the typhoid abscess and the relationship between the abscess and pearly tumor can at best be but speculated on. That the cholesteatoma lying in the depths of the frontal lobe grew from an embryonic cell rest is the only reasonable certainty connected with the whole consideration. It is my belief that the infection was implanted, either by coincidence or otherwise, on an already actively growing tumor.

DR. JOSEPH E. J. KING, New York: My two cases were included in Dr. Bucy's paper on this subject. The first case was seen in 1923. X-ray films were inspected before examination of the patient. The skull defect was so like that of Dr. Cushing's case reported in the May 1922 issue of *Surgery, Gynecology and Obstetrics* that I was able to make a pre-operative diagnosis. Dr. Cushing stated that a diagnosis should be made before operation from the x-ray films alone in those cases of extradural epidermoid cholesteatoma presenting the typical skull defect. This defect has a scalloped border or margin, which is very dense and hard. When seen on edge, as when looking at a saucer edgewise, the superimposed margins of the defect appear as a very dense line. The lesion arises in the diploe, destroys the inner table of the skull, and thins the outer table so that it may even be perforated at certain points. It may attain a very considerable size. The lesion in the first case was almost identical with that of Dr. Cushing's, except that it was somewhat smaller. It was completely removed. The second case was one in which the lesion involved the posterior fossa. It showed a similar skull defect and was diagnosed before operation. It was removed by morcellation for the reason that it could not be extirpated *en masse*. The first patient was operated on about thirteen years ago and the second about three years ago. Both are doing well and have shown no signs of recurrence.

DR. WALTER E. DANDY, Baltimore: These tumors develop from congenital rests; they are therefore of very slow growth, for most of them are found in adult life. In our cerebellar approach for trigeminal neuralgia, ten of these tumors have been encountered in the cerebellopontile angle and were presumably the cause of the pain. They are small tumors, just pressing on and setting off the zone in trigeminal neuralgia. None of these tumors would have been found had the temporal approach been used for section of the sensory root; and, since the tumors are small, they can be removed with almost no risk. Later they would doubtless have caused signs and symptoms of intracranial pressure and would have been far more difficult of complete removal.

DR. J. GRAFTON LOVE, Rochester, Minn.: In one of our patients, a 2½ year old child with a tumor in the cerebellar lobe, there was found at operation what appeared to be grossly an abscess. A culture was taken, from which a pure streptococcus was obtained. At the time of the operation the tumor had the characteristics of an abscess. It was drained as an abscess, and no extirpation was attempted. The child, unfortunately, died five days following operation from markedly increased intracranial pressure. I am glad Dr. Sachs emphasized the importance of total removal, which we didn't have the time to emphasize. If the capsule, which is the active part of these tumors, isn't removed, one can look forward to a recurrence.

---

**Diphtheritic Laryngitis.**—Diphtheritic membrane may form in the fauces, and spread to the larynx, or it may be present in the larynx alone. The term "true croup" is applied to diphtheritic laryngitis. The symptoms are those of diphtheria with laryngeal obstruction in addition. The child is ill and pale, with a significant bluish tinge of the cheeks and lips. The breathing is noisy, and there is indrawing of the intercostal spaces and upper abdomen, indicating the degree of respiratory obstruction. Spasm of the larynx will aggravate symptoms. The cervical glands are enlarged. Examination of the throat may show membrane on the fauces. In its absence it is essential to examine the larynx with the direct laryngoscope. No anesthetic is necessary or advisable. Treatment is that of diphtheria.—Crooks, James: *Surgical Aspects of Croup in Childhood, Practitioner* 137:709 (Nov.) 1936.

## Clinical Notes, Suggestions and New Instruments

### SUBCUTANEOUS EMPHYSEMA IN ASTHMA

JOHN M. SHELDON, M.D., AND WILLIAM D. ROBINSON, M.D.  
ANN ARBOR MICH.

Subcutaneous emphysema is a rare complication of asthma. Only nine cases<sup>1</sup> have been reported since Watson<sup>1</sup> first described the complication in 1885. Because of the paucity of information concerning this condition, we report the following case:

#### REPORT OF CASE

J. B., a boy aged 16 years, admitted to the University Hospital, Oct. 18, 1935, complained of shortness of breath of seven days' duration. He described the dyspnea as expiratory. The attacks were accompanied by an audible wheeze and terminated in cough productive of small amounts of white frothy sputum. The first asthmatic paroxysm occurred in June 1934. Since then he had been troubled from June to October of each year. Grain dust and hay dust were thought to initiate respiratory symptoms. The past history was negative. A maternal uncle was known to have asthma.

When he was examined the patient was having a mild asthmatic attack. The pulse rate was 132 per minute, the

and one subcutaneous injection of 0.3 cc. of epinephrine 1:1000 solution. Following this medication, clinical manifestations of asthma were alleviated. Thirty-six hours after admission crepitation typical of subcutaneous emphysema was noted over the left anterior thorax from the midline to the posterior axillary line, in the left upper quadrant of the abdomen, in the axilla, and in the anterior and posterior triangles of the left side of the neck. He stated that he had no symptoms referable to this subcutaneous emphysema. He remained comfortable and had no further asthmatic attacks, and the respirations remained normal throughout the rest of his hospital stay. The clinical evidence of subcutaneous air gradually decreased and completely disappeared in four days. A check-up examination eighteen days later was entirely negative, and no further respiratory symptoms occurred during the interval.

The urinalysis was negative. The blood Kahn test for syphilis was negative. The blood count showed 15,000 white blood cells per cubic millimeter, with a 7 per cent eosinophilia on admission and 13,400 white blood cells with a 9 per cent eosinophilia four days later. Intradermal tests to a group of ninety-five foods, fifteen epidermals and forty miscellaneous inhalant allergens were nonreactive. Scratch tests to thirty-one pollens were negative with the exception of timothy and long and short ragweed, which were markedly positive. The Pirquet test with 0.1 cc. of old tuberculin 1:10,000 was negative. Sputum examination on admission showed Curschmann's spirals and many eosinophils in the (Wright) stained smear.

Roentgen appearance forty-eight hours after patient's admission. a, postero-anterior view; b, lateral view; c, right anterior oblique view. Arrows point to extravasated air.

respiratory rate 32 per minute and the blood pressure 116 systolic, 70 diastolic. His stature was average. The state of nutrition was good. Excessive lacrimation, seropurulent nasal discharge and a postnasal drip were present. Numerous musical râles and rhonchi were heard throughout the lung fields. No subcutaneous emphysema was present. The remainder of the physical examination was of no diagnostic significance.

During the first twenty-four hours in the hospital he was given N-methyl-cyclohexenylmethylmalonylurea, 260 mg. orally,

A frontal stereoscopic film (a in the illustration) of the chest forty-eight hours after admission showed subcutaneous and subfascial emphysema of the left shoulder area. Air was present in the left side of the neck along the deep fascia extending into the mediastinum. The mediastinal emphysema was small in amount but particularly noticeable along the pericardium. There was air in the lower portion of the right side of the neck mesially. Lateral and right anterior oblique films (b and c in the illustration) demonstrated emphysema in the axillary fossa, around the acromion and the scapula on the left. In the mediastinum, air was visible anterior to the ascending arch of the thoracic aorta, over the pericardium in the superior mediastinum and posteriorly between the hilus and the aorta. Roentgen studies in all projections taken ten days after the appearance of emphysema were negative, showing complete absorption of the previously extravasated air.

#### COMMENT

The mechanism of production of subcutaneous emphysema has been proposed by Kelman<sup>2</sup> as follows: Increased intrapulmonary pressure first causes a vesicular emphysema of the peripheral alveoli, which have less support from surrounding lung tissue than do the more central alveoli. Increased pressure may then cause a rupture of the distended marginal

vesicles, with an escape of air under the visceral pleura. Since the pleura offers greater resistance to escaping air than does the pathway along the blood vessels, the course of the air is directed toward the hilus. From the hilus the air follows the pleural reflections and enters the tissues of the anterior mediastinum. The air may then spread up or down, chiefly along the pathway of the great vessels. Joannides and Tsoulos,<sup>3</sup> on introducing air under pressure into the bronchi of dogs, found the weakest point of the lung to be at the hili where the visceral and parietal pleurae meet. Berkley and Coffen,<sup>4</sup> in a study of necropsy material of bronchopneumonia and generalized interstitial emphysema, described two routes for the escape of air from the lungs into the subcutaneous tissues. In the intrapleural route it was necessary for the air to escape through both the visceral and parietal pleurae. These authors felt that this was a rare pathway but could occur without pneumothorax when extensive adhesions were present. Mediastinal emphysema would not occur under these circumstances. In the more common extrapleural route, air coursed from the ruptured air sac along the blood vessels to the hilus, then to the posterior mediastinum and the anterior mediastinum, and then entered the subcutaneous tissues of the neck by following the blood vessel sheaths through the deep fascia. From these studies it would seem that, in the asthmatic patient, alveolar rupture could occur either at the hilus or at the periphery of the lung with migration of air through the tissues as described.

Alveolar rupture must be dependent on both increased intrapulmonary pressure and decreased strength of the alveolar walls. The asthmatic paroxysm alone will raise the intrapulmonary pressure, but additional coughing, straining or lifting is probably necessary to raise it to the point of alveolar rupture. The relatively rare occurrence of this complication in asthmatic patients, in spite of their violent respiratory effort, suggests that congenital or acquired weakness of the alveolar walls may be the more important factor. The age of the individual may be important in this phenomenon. The reported cases have occurred in young persons, from 8 to 25 years of age. It has occurred more often in patients having seasonal or infrequent attacks of asthma. The acuteness or severity of the attack and the sex of the patient are apparently of no significance.

Subcutaneous emphysema that occurs in asthma carries a good prognosis. No fatalities have been reported. The condition is self limited, with spontaneous recovery in from four to fourteen days. Treatment is entirely supportive.

#### SUMMARY

Subcutaneous emphysema is a rare complication of asthma. Only ten cases, including our own case, are known to us. The prognosis of the reported cases of subcutaneous emphysema, occurring in the asthmatic patient, is good.

#### TORTICOLLIS OF UNUSUAL ORIGIN

LAURENCE H. MAYERS, M.D., CHICAGO

The patient here studied, a girl of 19, has had wry-neck since puberty. A unique feature of her condition is that she can straighten her head at will but can maintain the position only as long as she can hold her breath. She can neither breathe nor swallow when her head is in a natural position.

#### REPORT OF CASE

**History.**—The patient's parents, concerned over her noticeable habit of carrying her head to the right, a defect so pronounced as to be a deformity, had consulted a surgeon, who advised an operation to correct the defect.

As a child the patient was normal. She was unusually active and her health was always good. The removal of adenoids when she was 7 years old was her only operation. Typhoid at the age of 10 was without after-effects. She menstruated at 12 and the following year she began gradually to gain in weight. At 14 she had measles.

It was at the age of 14 that the patient became conscious of a tendency of the head to incline to the right. There was no

acute pain, and the inclination of the head came on gradually. In a few months the condition became more pronounced, but still the pain was not acute. At this time she was still in school and states that she was more conscious of the condition after exercise.

When she was 17 the condition of the neck became so annoying that a physician was consulted. He informed her that she had wry-neck and prescribed a tonic and calcium. These were without effect. A little later her parents took her to another physician, who recommended sun lamp treatments three times a week for several weeks. Again there was no relief and a consultation followed. The consultant prescribed stretching treatments and massage and by these she was greatly benefited.

At the present time the patient's life is routine and not at all strenuous. She sleeps well and her habits are wholesome.

**Examination.**—It was observed that the patient could straighten her head when she so desired but could not hold it long in that position. When it was held straight by force, she jerked it away. When asked why she did so she replied "So I can breathe." It was then discovered that she could neither breathe nor swallow when her head was in the natural position; that is, when her neck was straight. An injury was indicated, but of such an occurrence the patient had no knowledge.

The mother was appealed to and an accident at birth was recalled. This was a breech presentation with forceps on the

A, normal odontoid centrally located and symmetrical alignment of first and second cervical vertebrae. B, odontoid displaced to the right and asymmetrical alignment of lateral vertebral margins.

aftercoming head. The child had difficulty in breathing for several days and the attendants at times thought she would not survive. However, these difficulties were soon forgotten. The child's head kept its normal position until puberty, when the increase in weight already mentioned began.

Several roentgenograms of the cervical spine had previously been taken but there were no abnormalities. These, however, had not included a picture of the odontoid process. A roentgenogram was made of this process, which revealed that the odontoid process was shifted to the right.

#### COMMENT

Several circumstances about this case are unique. The patient was not seeking relief for herself; her parents were trying to correct the condition because of the girl's appearance.

It is unusual to see a deformity of this nature in which the patient can straighten her head by her own efforts but can maintain the position only for as long as she can hold her breath.

It is interesting also to note that the girl cannot swallow when her neck is straight but has to turn her head sidewise in order to swallow.

The history of the injury was given as an afterthought, the patient never having heard of the accident. The head remained straight until puberty, and during this time there was a sudden increase of weight. Growth was rapid and weight reached 160 pounds (72.6 Kg.) at the age of 14 years.

4. Berkley, H. K., and Coffen, T. H.: Generalized Interstitial Emphysema and Spontaneous Pneumothorax as Complications of Bronchopneumonia, *J. A. M. A.* 72: 535 (Feb. 22) 1919.

From the Department of Internal Medicine, Northwestern University Medical School.

In my opinion, the turning of the head at this age, making swallowing and breathing possible only when the head is inclined to the right, is the result of sudden changes in the structure of the neck during adolescence, especially the growth of the thyroid. The routine x-ray examination did not reveal the pathologic condition because the odontoid process was not included in the field.

Whether the explanation offered is right or wrong does not interfere with or alter the treatment. The one purpose it served was to prevent an operation that was doomed to failure.

#### VISUALIZATION OF THE AMOUNT OF RESIDUAL URINE

EDWIN BEER, M.D., NEW YORK

Since the introduction of excretory urography, a simple method of demonstrating the ability of the bladder to empty

that an excretory urogram is indicated in all obstructive conditions at the neck of the bladder to determine the physiologic and anatomic state of the upper urinary tract, no additional measures are necessary to visualize the ability of the bladder to empty itself.

Before taking the last roentgenogram, the patient is allowed to void as completely as possible, and then the picture is taken and a graphic expression of the residue left in the bladder after voiding is obtained. This simple procedure avoids all instrumental interference with the bladder, avoids the dangers of infection, trauma of too sudden emptying of the organ and the occasional complete obstruction that follows the passing of a catheter. Even though one does not obtain an accurate quantitative measure of the residual amount, it gives a sufficiently clear picture to allow the student to obtain a satisfactory idea of the amount of residue and the topography at the neck of the bladder, without applying any measures other than excretory urography (figures 1 and 2). This procedure has been adopted as a routine in my service for all patients, usually

## Special Article

### THE PHARMACOPEIA AND THE PHYSICIAN

#### LOCAL MEDICATION OF THE UPPER RESPIRATORY TRACT

CLYDE A. HEATLY, M.D.  
ROCHESTER, N. Y.

*This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.*

The use of local medications by the general practitioner in the treatment of diseases of the upper respiratory tract should be restricted for the most part to acute infections. It is to be emphasized that attempts to treat chronic disorders by such measures are fraught with serious danger until the diagnosis of the underlying pathologic condition has been thoroughly established. This as a rule requires examination by a specialist in this field. All too frequently cases are encountered in which local medications have been carried out over long periods before a serious underlying infection or new growth has been discovered. The resulting loss of time commonly leads to serious or even fatal consequences.

#### ACUTE RHINITIS

The ideal therapeutic aims of local medication in acute rhinitis are the reduction of nasal congestion, the promotion or restoration of ciliary function and the destruction of pathogenic organisms. Recent experimental studies by Proetz,<sup>1</sup> Lierle and Moore,<sup>2</sup> Fenton and Larsell<sup>3</sup> and other workers have demonstrated that many of our accepted local preparations are actually destructive to epithelium and favor infection by impairing ciliary activity. In the light of these investigations ephedrine sulfate (from 0.5 to 3 per cent solutions with 1 per cent as the usual strength) in physiologic solution of sodium chloride most closely meets the ideal therapeutic requirements by producing prompt relief of congestion without slowing the ciliary activity or destroying the epithelium. The commonly used nasal oils, containing liquid petrolatum, eucalyptol, menthol, camphor and thymol, all definitely slow or paralyze ciliary activity despite their recognized soothing properties. As vehicles for ephedrine, therefore, they would appear from these studies actually to lessen its therapeutic value. The commonly used silver colloids mild protein silver and neosilvol (10 per cent solutions) have been found experimentally by McMahon<sup>4</sup> and by Fenton and Larsell to destroy epithelium and to impair ciliary action. Nevertheless they will continue to be widely used for their recognized empirical value. Merthiolate

(1:5,000 solution) is commonly combined with ephedrine solutions for its antiseptic properties, but it also has a paralyzing effect on cilia. It is thus evident that many commonly used preparations may combine desirable with at least experimentally proved undesirable effects on the nasal mucous membranes. Epinephrine even in a dilution of 1:5,000 causes a slowing of ciliary activity. Furthermore, the marked congestion that follows its transient vasoconstricting action has led most rhinologists to abandon its use in acute rhinitis. It should be emphasized that nasal solutions containing menthol should never be employed in infancy because of their possible toxic effect. The indiscriminate use of liquid petrolatum as nasal drops in infancy is not entirely without danger in view of the numerous reported cases of lipoid pneumonia from accidental inhalation. The usefulness of nasal drops will be increased by bending the head backward in the Proetz position or in the lateral head-low position described by Parkinson.<sup>5</sup> The use of nasal douches is not recommended in acute rhinitis because of the possibility of inducing an otitis media. Bland ointments of zinc or boric acid are soothing when troublesome irritation of the nasal vestibule and upper lip is present.

#### CHRONIC RHINITIS

Chronic rhinitis includes such a wide variety of causes that careful study by a competent rhinologist is required before treatment can be outlined. A chronic discharge may be caused by sinusitis, infected adenoids, polyps, foreign bodies or malignant growths. It may be a local manifestation of constitutional disease, such as congenital syphilis or diphtheria, or the result of atrophic or hypertrophic changes in the nasal mucous membranes. Successful management commonly requires surgery or special types of treatment, and simple local medication consequently plays a relatively minor rôle. Certain preparations are commonly used in this work. Oily solutions containing menthol and camphor (1 per cent) in liquid petrolatum reduce congestion and lessen irritation (prescription A). Mild

may be similarly used. Preliminary cocainization will be required for this as well as for many surgical procedures. Cocaine hydrochloride solution of suitable strength is usually employed. It should not be used in children and should always be applied with caution because of the alarming or even fatal reaction that may follow in sensitive individuals. It has been established that preliminary medication before the use of cocaine greatly lessens its toxic effects. Morphine (from 0.01 to 0.016 Gm.) with atropine sulfate (from 0.00065 to 0.0004 Gm.) may be given thirty minutes before operations in which it is used. The barbiturates (barbital 0.65 Gm., phenobarbital 0.2 Gm. or pentobarbital 0.1 Gm.) given by mouth one hour before are also effective in lessening possible toxic effects. Pantocain has in my experience proved to be a safe and effective substitute for surface anesthesia in children. Nasal irrigations, carefully given, may prove of value in certain conditions, such as atrophic rhinitis. Mixtures containing salt, soda, and dextrose (1 teaspoonful of each in a pint of warm water) are commonly used. Hydrogen peroxide is helpful in such cases in loosening the crusts, preliminary to their removal by irrigation. Tampons moistened with peroxide may also prove useful in controlling epistaxis.

#### ACUTE INFECTION OF THE THROAT

Acute infections may attack the throat in the form of an acute pharyngitis or more diffusely as an acute tonsillitis of the catarrhal or follicular variety. Sometimes the staphylococcus or pneumococcus is responsible but as a rule the streptococcus is the causative organism. Most of the severe cases, especially the epidemic septic type, are due to the beta-hemolytic variety. The throat is affected in many acute diseases, notably scarlet fever, measles, diphtheria, Vincent's infections or the secondary stages of syphilis. Acute inflammation followed by ulceration may result from granulocytopenia or acute leukemia and the true cause be overlooked, especially in the early stages, unless a leukocyte count is made. It is evident therefore that careful diagnosis supported by laboratory studies is necessary for successful therapeutic management.

#### LOCAL TREATMENT

In the early stages of acute pharyngitis the local application of silver nitrate (from 5 to 20 per cent), mild protein silver (10 or 20 per cent) or Mandl's solution often gives relief. Vigorous swabbing, however, should be avoided. Gargles, so frequently prescribed, are often useless, especially in children, because the contraction of the tongue and pharyngeal muscles prevents the solution from reaching the inflamed parts. They may, however, be used in the form of salt and soda, one-half teaspoonful each in a glass of warm water or Dobell's solution, 2 tablespoonfuls in a glass of warm water. In the more severe infections the use of hot salt and soda irrigations will be more effective. Lozenges containing small quantities of menthol, camphor, guaiac and codeine, orthoform tablets or calcidin-anesthesin troches lessen the discomfort in mild cases.

In acute tonsillitis the most effective local treatment consists in irrigation of the throat every two hours with a warm solution containing 1 teaspoonful of sodium chloride and sodium bicarbonate in 1 pint of water. Warm glucose solution (50 per cent) made with "Corn Syrup" 1 part and water 2 parts is also effective. The

patient's head should be inclined forward with the mouth open so as to facilitate the flow. When irrigations are not possible nor well tolerated a similar warm solution of salt and soda, potassium permanganate (1:5,000 solution) or acetylsalicylic acid (five tablets crushed in a glass of water) may be used as a gargle.

#### C. Compound Glycerite of Iodine

B	Iodine .....	0.5 Gm.
	Potassium Iodide .....	1.6 Gm.
	Oil of Peppermint .....	0.5 cc.
	Glycerin .....	30.0 cc.

M. Label: Topical application.

The practice of frequent and vigorous swabbing is decidedly not recommended. Semisuspension by raising the head by means of the hands placed over each mastoid process may be employed effectively to prevent swallowing when severe dysphagia is present.

#### FUSOSPIROCHETAL ANGINA (VINCENT'S ANGINA)

The common acute infectious disease fusospirochetal angina is due to a symbiosis of organisms including a fusiform bacillus, a widely coiled spirochete (*Spirochaeta vincenti*), a vibrio and a coccus. These organisms are anaerobic and commonly multiply in the crevices about the teeth, in pockets under the gums or in the depths of the tonsillar crypts. Pathologic studies indicate that the spirochete penetrates deeply, produces the often extensive destruction of tissue characteristic of the lesion and is the chief agent responsible for the spread of the disease. The bacillus predominates in the more superficial zone and produces the fetor. Since the causative organisms are anaerobic, the fundamentals of treatment require open drainage with free access of air, the local application of oxidizing agents and local or general arsenic therapy to destroy the spirochetes.

A survey of the literature indicates that in the mild or diphtheroid type of lesion any antiseptic will cure. Silver nitrate (from 10 to 20 per cent), tincture of iodine, chromic acid (5 per cent), copper sulfate (10 per cent), gentian violet, methylene blue, acriflavine base and mercurochrome have all been used successfully in this type of lesion. For the more severe and widespread infections, however, active oxidizing agents and spirocheticides are essential. The external necrotic layer should be gently removed with a swab soaked with hydrogen peroxide. A fresh swab saturated with solution of potassium arsenite or arspenamine in glycerin (10 per cent solution) should then be carefully applied over the diseased area. The patient may be given a small quantity of either of these preparations with instructions to apply them locally at four hour intervals. Sodium perborate has also proved effective, used frequently in saturated solution as a gargle or in cases of stomatitis as a thick paste mixed with water and followed by rinsing the mouth with warm water about five minutes later. In particularly severe cases or in those which fail to respond to local treatment within seventy-two hours, an intravenous injection of neoarsphenamine is advised. Intravenous therapy is especially indicated when there is an associated bronchitis suggesting an extension of the infection to the lower respiratory tract. Bismuth preparations, notably bismuth and sodium tartrate in 1.5 per cent glycerinate solution for topical application and 1.5 per cent aqueous solution for intramuscular use or bismuth tartrate in the form of a salve emulsion (30 per cent), used daily, have been enthusiastically advocated by certain European and South American observers as being more sedative, less

ic and more powerful than the arsphenamine group. ict precautions should be urged in order to protect er members of the household from the infection.

#### ACUTE LARYNGITIS

The therapeutic indications in acute laryngitis require control of inflammation, the release of spasm hich so commonly characterizes this malady in early ildhood), and the relief of obstructive dyspnea. The ter symptom is of course limited to severe infections d may require intubation or tracheotomy. The possi- ility of laryngeal diphtheria must be carefully investi- ted in all cases. The closed lymphatic system of the erior of the larynx limits absorption and accounts for e relatively mild constitutional reaction that is com- only present.

Complete rest in a warm room with even, moist tem- perature (70 F.) is essential to prompt control of the infection. Vocal rest also is important. Steam inhala- tions to which compound tincture of benzoin (1 tea- spoonful to a pint of water) is added constitute the most helpful local treatment. Menthol (0.65 Gm.) may be similarly employed (prescription D). These may be given directly at three hour intervals and a steam kettle should be kept going constantly in the room. A croup tent is most effective in young children. Hot applica- tions are beneficial, especially when a tendency to spasm is present. Cold applications may be soothing in adults when tenderness over the larynx is noted. Irritative

#### D. Mixture of Menthol, Camphor, Pine Oil and Eucalyptus

R	Menthol .....	15.0 Gm.
	Camphor .....	15.0 Gm.
	Oil of Dwarf Pine Needles.....	30.0 cc.
	Oil of Eucalyptus.....	30.0 cc.

M. Label: 1 teaspoonful in 1 pint of water—steamed and inhaled.

cough should be controlled by small doses of codeine sulfate. Small doses of phenobarbital are also of value in young children. When laryngeal spasm is present (croup), relaxation may be further aided by the use of emetics. For a child of 2 years, for example, syrup of ipecac, one-half teaspoonful every fifteen minutes until vomiting occurs, is the safest drug. Smaller doses (5 drops every two hours) may help to reduce the recurrence of spasm without causing emesis. Concomitant infection in the nose or throat requires appropriate local treatment. The diet should be light and fluids should be forced freely. Swabbing of the larynx may cause alarming spasm and should be avoided.

Chronic hoarseness should never be treated by the general practitioner. A serious lesion may otherwise pass unrecognized with disastrous results.

#### DISEASES OF THE EAR

Few ear conditions are suitable for treatment by the general practitioner. In acute external otitis (boils) the external auditory canal may be gently cleaned with alcohol and then packed lightly with a narrow gauze

#### E. Diluted Solution of Aluminum Acetate

R	Burow's solution .....	60.0 cc.
	Water .....	120.0 cc.

M. Label: Drop warmed solution in canal every 2 hours or apply on gauze wick.

wick soaked with aluminum acetate (saturated solu- tion), ichthammol in glycerin (10 per cent) or mer- cresin (prescriptions E, F and G). Heat should be applied as constantly as possible and gives great relief. Vaccines may be of value in recurrent cases. Fungus infections (otomycosis) are best controlled by daily

instillations of a 2 per cent solution of salicylic acid in alcohol (70 per cent) together with the administration of potassium iodide by mouth. Infections caused by *Bacillus pyocyaneus* respond to acetic acid (2 per cent solution). When earache is due to an acute catarrhal

#### F. Glycerite of Phenol and Ichthammol

R	Phenol .....	0.65 Gm.
	Ichthammol .....	7.5 Gm.
	Glycerin .....	30.0 cc.

M. Label: Drop into canal every two hours or apply directly by means of gauze packing.

#### G. Ointment of Salicylic Acid and Sulfur

R	Salicylic Acid .....	0.6 Gm.
	Precipitated Sulfur .....	30.0 Gm.
	Petrolatum .....	30.0 Gm.

M. Label: Apply locally.

inflammation of the tympanic membrane, warm drops of phenol in glycerin (from 5 to 10 per cent solution) repeated if necessary at three hour intervals for two or three doses often give relief.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS ADOPTED THE FOLLOWING REPORTS.  
HOWARD A. CARTER, Secretary.

### PORTABLE BOVIE SURGICAL UNIT ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, Cincinnati.

This unit is a simple, efficient equipment designed for electro-surgery. It is mounted in a sturdy cabinet of walnut finish.

The unit has a four gap circuit, multiple connections for operating instruments, a current selector switch, sterilizable control handles, instruments and instrument rack.

The firm submitted performance tests on this machine showing that the machine had been operated intermittently for one-half hour. The temperature rise of the transformer and spark gap was within the limits of safety established by the Council. The Council's investigator confirmed the evidence submitted by the manufacturer.

The firm has also informed the Council that this unit is identical to the Junior Bovie Electro-Surgical Unit, already accepted, ex-

Fig. 1.—Portable Bovie Surgical Unit.

Fig. 2.—Schematic diagram of circuit.

cept that the portable model is slightly more powerful. It is not equipped for medical diathermy.

The Council on Physical Therapy voted to include the Portable Bovie Surgical Unit in its list of accepted devices.

# FISCHER MODEL "SWDI" SHORT WAVE APPARATUS ACCEPTABLE

Manufacturer: H. G. Fischer & Company, Chicago.

This device is recommended for medical and surgical diathermy. It produces a high frequency electric current suitable for generating heat locally within the body tissues, and it may also be used for electrosurgery. The device is obtainable in wavelengths of 6, 12, 18 or 24 meters. If the physician desires, the wavelength may be changed merely by substituting a different oscillator unit, an operation requiring only a few minutes.

The electric field method or the electromagnetic induction method of application may be practiced with this short wave diathermy. The electrodes or applicators furnished with the apparatus consist of cuffs, pads and insulated cable. The circuit is of a well known type having two oscillator and two rectifier tubes. The patient's circuit is inductively coupled to the tank circuit. A variable condenser is used to tune the patient's circuit to electrical resonance. When this machine is operated under full load, it draws not more than 1,000 watts. Since no reliable method has been proposed to measure the output of energy available to the patient, this value is not given.

When making application for consideration, the manufacturer submitted evidence substantiating the heating ability of the unit. Observations were taken using 6, 12, 18 and 24 meter high frequency energy for both electric and electromagnetic field methods. For the electric field method, cuffs were applied to the thigh—one posterior to the hip and the other anterior to the knee. The cuff electrodes used in the investigation were

removed, leaving the rubber cannula in situ. Temperature measurements were taken by means of thermocouples of the hypodermic needle type and introduced through the cannula. The third thermocouple placed on the skin surface underneath the cuffs was used to measure skin surface temperature. The junctions were immersed in ice enclosed in a quart vacuum bottle. The readings were observed on a Leeds and Northrup Portable Potentiometer. The thermocouples were calibrated in degrees Fahrenheit, against a Bureau of Standards thermometer. Initial temperatures were taken and then each subject was submitted to a twenty-minute application of short wave diathermy energy of maximum current strength at tolerance. At the end of this period, the temperatures were again recorded. Temperatures were observed at intervals of one minute until the temperature began to drop. The highest

## Results of Observations

Tech. Wavelength	Muscle Temperature		Subcutaneous Temperature		Skin Surface Temperature		Oral Temperature	
	Initial	Final	Initial	Final	Initial	Final	Initial	Final
Cuff 24	99.55	104.27	95.85	102.85	91.73	98.20	98.33	99.00
Coil 24	99.07	106.05	97.72	105.55	96.08	98.71	98.71	99.00
Cuff 18	100.05	105.73	97.03	103.35	92.52	97.98	98.33	99.00
Coil 18	97.98	106.72	94.82	105.77	93.62	99.08	98.70	99.00
Cuff 12	100.13	106.45	97.48	103.98	93.13	98.42	98.50	99.00
Coil 12	99.73	106.60	97.33	105.83	94.55	99.37	98.67	99.00
Cuff 6	99.93	106.58	97.12	103.68	93.33	98.40	98.50	99.00

Fig. 1.—Fischer Model "SWDI" Short Wave Apparatus.

temperature attained was recorded as the final temperature in each instance. Then the thigh was permitted to cool until the temperature dropped to or near the initial temperature and the observation repeated with a different unit. Each temperature reading in the table is the average of six observations. Data on the temperature rise when pad or air-gap electrodes were employed were not submitted. The temperature rise of

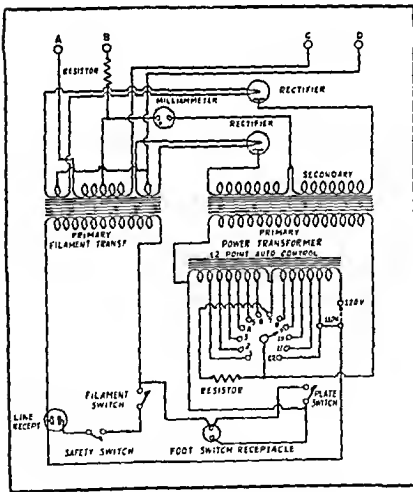

Fig. 2.—Fischer "SWDI" power unit.

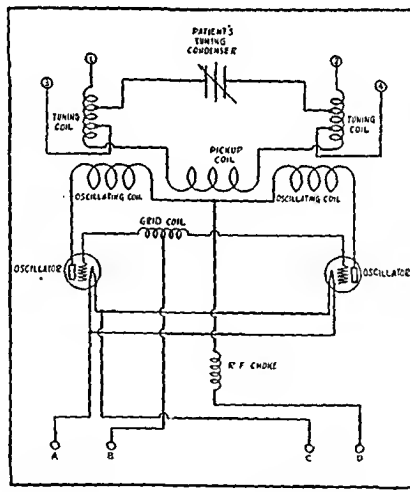

Fig. 3.—Fischer "SWDI" 6 oscillator unit.

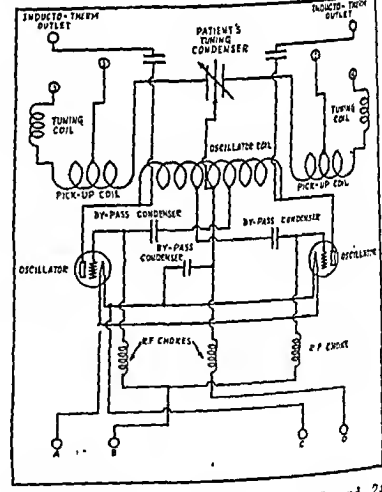

Fig. 4.—Fischer "SWDI" 12, 18 and 24 oscillator unit.

made of metal surrounded by thick protecting rubber. Several layers of toweling or felt, or both materials, were placed next to the skin to absorb perspiration and also to permit suitable spacing of the electrodes. In the case of the electromagnetic field method, a heavy insulated coil was wrapped around the thigh and separated from the skin by one-half inch of toweling and felt.

The human subjects were all vigorous, adult, male medical students, ranging in weight from 150 to 180 pounds. Two trocars placed in hard rubber cannulas were inserted into the thigh. One was introduced at right angles to the thigh and straight down into the depth of the muscle tissue until the instrument was at an approximate depth of 2 inches or until the femur was encountered. The second was introduced as nearly parallel to the skin as possible and subcutaneously at an approximate depth of one-eighth inch. The trocars were

the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. The shipping weight of the apparatus is about 170 pounds.

The unit was investigated in a clinic acceptable to the Council under actual clinical conditions. There did not appear to be any appreciable advantage of one wavelength energy over another of those four wavelengths investigated when the cuff or coil technic was used. The six meter wavelength is not adaptable for coil technic. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is much less than with conventional diathermy.

Evidence was presented by the firm to substantiate the claims made for hyperpyrexia.

The machine was installed in a clinic acceptable to the Council and operated under actual clinical conditions. It was reported

is giving satisfactory service. In view of the favorable report based on the performance of this unit when cuff electrodes or coil technic was used, the Council on Physical Therapy voted to include the Fischer Model "SWD1" (6, 12, 18 and 24 meter) Short Wave Apparatus in its list of accepted devices.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.  
PAUL NICHOLAS LEECH, Secretary.

#### KONSYL NOT ACCEPTABLE FOR N. N. R.

Konsyl, which is stated to be "the gelatinous-forming part of *Plantago Ovata*" prepared by mechanical removing of the psyllium seed coating, was presented for the Council's consideration by National Vaccine and Antitoxin Institute, Washington, D. C., in 1934. Soon thereafter the Council was notified that the firm name had been changed to Burton, Parsons & Co.

The first question considered by the Council was the eligibility of the product for a proprietary name. The Council held that there was not sufficient evidence to show eligibility of a preparation of psyllium seed, deprived of the greater part of its oil and woody fiber, to the use of a coined proprietary name.

The firm submitted an advertising circular which the Council found to contain various unwarranted claims. When these were reported to the firm, it sent a revised circular from which the specific claims objected to were deleted. The firm, however, offered no adequate evidence to justify the use of a coined proprietary name for this product. For this reason, the Council declared Konsyl unacceptable for inclusion in New and Nonofficial Remedies.

#### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**PERCOMORPH LIVER OIL.**—*Oleum Percomorphum*.—A mixture containing the fixed oils obtained from the fresh livers of the percomorph fishes, principally *Xiphias gladius*, *Pneumatophorus dio*, *Thunnus thynnus* and *Stereolepis gigas*—sometimes also *Neothunnus macropterus*, *Katsuwonus pelamis*, *Sarda chiliensis*, *Germo alalunga*, *Thunnus orientalis*, *Scomber scombrus*, *Seriola dorsalis*, *Lutianus campechanus*, *Epinephelus morio*, *Roccus lineatus*, *Cynoscion nobilis*, *Eriscion macdonaldi*, *Epinephelus analogus*, *Stereolepis ishinagi* and *Sphyræna argentea*, containing 50 per cent of cod liver oil. It is biologically assayed to have a potency of not less than 60,000 units of vitamin A (U. S. P.) per gram and of not less than 8,500 units of vitamin D (U. S. P.) per gram.

**Actions and Uses.**—Same as those of cod liver oil. See General Article Cod Liver Oil and Cod Liver Oil Preparations, N. N. R. 1936, p. 449.

**Dosage.**—Prophylactic, for normal infants 10 drops daily; curative, and in severe conditions, to 20 drops daily. The product is marketed with a dropper designed to deliver 3 drops to the minim.

Percomorph liver oil, 50%, in cod liver oil, is a yellow to brownish yellow, oily liquid. It has a slightly fishy but not rancid odor and a fishy taste. It is slightly soluble in alcohol but is soluble in ether, chloroform, benzene, carbon disulfide and ethyl acetate. The specific gravity is from 0.922 to 0.930 at 25°C. The refractive index is from 1.480 to 1.485 at 20°C.

A solution of one drop of the oil in 1 cc. of chloroform, when shaken with one drop of sulfuric acid, acquires a blue color, changing to violet, dark green, and finally brown. Treat 5 cc. of oil with 5 cc. of benzene and centrifuge for twenty-five minutes at 25°C.; no precipitate forms and a clear solution remains.

Fill a tall, cylindrical, standard oil-sample bottle of about 120 cc. capacity with percomorph liver oil, 50%, in cod liver oil, at a temperature between 23 and 28°C., stopper, and immerse the bottle in a mixture of ice and distilled water for five hours: the oil remains fluid and forms no deposit.

Dissolve 2 Gm. of percomorph liver oil, 50%, in cod liver oil in 20 cc. of a mixture of equal volumes of alcohol and ether, which previously has been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T. S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not more than 1 cc. of tenth-normal sodium hydroxide is required (*free acid*). The amount of unsaponifiable matter as determined by the method of U. S. P. XI, page 446, is not less than 3.5 per cent nor more than 7 per cent (it is semisolid in appearance). The saponification value as determined by the method of U. S. P. XI, page 445, is not less than 174 and not more than 186. The iodine value as determined by the method of U. S. P. XI, page 445, on 0.18 to 0.20 Gm. of sample, accurately weighed, is not less than 145 and not more than 180.

The undiluted fixed oil obtained from the fresh livers of the percomorph fishes and used in the preparation of percomorph liver oil 50 per cent in cod liver oil conforms to the following constants as determined by methods of U. S. P. XI: specific gravity, from 0.924 to 0.930 at 25°C.; refractive index, from 1.484 to 1.490 at 20°C.; free acid in 2 Gm., equivalent to not more than 1 cc. of tenth-normal sodium hydroxide; unsaponifiable matter, not less than 7 nor more than 13 per cent (semi-solid in appearance); saponification value, not less than 168 nor more than 182; iodine value, not less than 145 nor more than 180.

**Mead's Oleum Percomorphum.**—A brand of percomorph liver oil—N. N. R.

Manufactured by Mead Johnson & Co., Evansville, Ind. No U. S. patent or trademark.

**Mead's Oleum Percomorphum, 50% (In Capsules).**—Each capsule contains 10 drops (0.222 Gm.) of Mead's Oleum Percomorphum, 50%, representing a vitamin potency of not less than 13,300 vitamin A units and 1,850 vitamin D units, U. S. P.

**COD LIVER OIL** (See New and Nonofficial Remedies, 1936, p. 450).

**Mead's Standard Cod Liver Oil** (formerly Mead's Newfoundland Cod Liver Oil) (See New and Nonofficial Remedies, 1936, p. 451).

The following dosage form has been accepted:

**Mead's Cod Liver Oil Fortified with Percomorph Liver Oil.**—A mixture of cod liver oil—U. S. P. and percomorph liver oil 5 per cent. It has a potency of not less than 6,000 vitamin A units (U. S. P.) per gram and of not less than 850 vitamin D units (U. S. P.) per gram.

**AZOCHLORAMID** (See New and Nonofficial Remedies, 1936, p. 228).

The following dosage form has been accepted:

**Azochloramid Solution in Triacetin 1:125.**—A solution containing Azochloramid 1 Gm. in 125 Gm. of triacetin (triacetin, a mixture containing 100 per cent glyceryl triacetate ( $\text{CH}_3\text{OOCCH}_2\text{—}$  for use in the preparation of azochloramid + volume of azochloramid in triacetin 1:125 diluted with 15 volumes of olive oil).

**DIPHTHERIA ANTITOXIN, BOVINE.**—An antitoxin differing from diphtheria antitoxin—U. S. P. in that it is made from the serum of cattle instead of from horse serum and is less potent.

Mulford Biological Laboratories, Sharp & Dohme, Inc., Philadelphia and Baltimore.

**Diphtheria Antitoxin (Bovine).**—An antitoxin derived from the blood serum of cattle immunized against diphtheria toxin. Diphtheria antitoxin (bovine) serves as an alternative to diphtheria antitoxin (equine) in the treatment of individuals giving a positive reaction to the ophthalmic test with diphtheria antitoxin prepared from horse serum. Marketed in packages of one 30 cc. ampule vial containing 5,000 units.

**POLLEN ANTIGENS-LEDERLE** (See New and Nonofficial Remedies, 1936, p. 35).

The following additional product, supplied in five vial packages representing series A, B, C and F as described in New and Nonofficial Remedies 1936, page 35, and in packages of three 3 cc. vials containing 100, 1,500 and 20,000 pollen units per cubic centimeters, respectively, has been accepted:

**Mixed Grasses Pollen Antigen-Lederle** (*June Grass, Orchard Grass, Sweet Vernal Grass, Red Top and Timothy, in equal parts*).

The following additional dosage form has been accepted:

**Rageweed Combined Pollen Antigen-Lederle.** Also marketed in packages of three 3 cc. vials containing 100, 1,500, and 20,000 pollen units per cubic centimeter, respectively.

**CONCENTRATED POLLEN ANTIGENS-LEDERLE** (See New and Nonofficial Remedies, 1936, p. 32).

The following additional product, supplied in five syringe packages representing series A, B, C and F as described in New and Nonofficial Remedies 1936, page 32, has been accepted:

**Mixed Grasses Concentrated Pollen Antigen-Lederle** (*June Grass, Orchard Grass, Sweet Vernal Grass, Red Top and Timothy, in equal parts*).

**PARATHYROID EXTRACT-LILLY** (See New and Nonofficial Remedies, 1936, p. 327).

The following dosage form has been accepted:

**Parathyroid Extract-Lilly.** 1 cc. Ampules: Each cubic centimeter contains 100 units.

## UTILIZATION OF DIFFERENT FORMS OF IODINE

Different forms of a number of dietary constituents are utilized with varying degrees of efficiency. Certain iron compounds, for example, are easily available to the organism and are well utilized for the formation of hemoglobin, whereas certain others are poorly utilized. Similar differences have been observed with respect to compounds of calcium and of copper. Because of the well known importance of iodine in animal nutrition, the problem of the relative efficiency of utilization of different forms of this element have received some attention. One of the earliest studies of the question<sup>1</sup> was made on a human subject consuming a diet low in iodine. The amounts of iodine retained in the body were determined by the "balance" method following the oral administration of various iodine-containing substances. The retention of iodine was found to be highest when this substance was supplied in the form of iodine-containing fats (liver oil) or potassium iodide; somewhat poorer retention was observed if iodine was supplied in the form of green vegetables (watercress or spinach) or sardines. Although this work may be open to possible criticisms with respect to the methods employed, there is nevertheless a definite indication that different forms of iodine are available to the organism in varying degrees.

Recently the problem has been reinvestigated in the rat<sup>2</sup> and in the laying hen.<sup>3</sup> In the former study, animals were fed a basal diet which uniformly produced goiter because of its low iodine content. The various iodine-containing substances to be investigated were added to the basal diet in quantities supplying equivalent amounts of iodine. The effect on the fresh and dry weight and the iodine content of the thyroid glands were determined as an index to the antigoitrogenic

value, and hence the degree of utilization, of iodine from the substance employed. The results indicated that iodine in the form present in milk, oysters and dried haddock was just as effective in preventing thyroid hypertrophy and in promoting the storage of iodine in the gland as was potassium iodide. Thus, no support is given by these results to the view that "food iodine" is superior to "inorganic iodine." Iodine supplied in the form of Irish moss was not as effective as were the other forms, suggesting that the iodine present in this substance is only partially available to the organism.

Similar evidence of differences in the availability of iodine from different substances was obtained in the studies on laying hens,<sup>3</sup> the amount of iodine appearing in the excreta and in the eggs serving as criteria of the effectiveness of the substance given. Little difference was found between the retention of iodine and the iodine content of the eggs after the administration of oyster shell, desiccated thyroid, sodium or potassium iodide, potassium iodate, diiodotyrosine or iodized olive oil. However, the iodine of iodosalicylic acid appeared to be only partially available. More than 70 per cent of the iodine administered in this form appeared in the excreta, whereas only 48 to 66 per cent of that given as the other compounds was eliminated. Likewise, the iodine content of the eggs from hens given iodosalicylic acid was decidedly less than that from the eggs of hens fed the other iodine-containing substances.

There are apparently distinct differences in the availability of iodine in various forms. These differences may not be of great significance as far as the dietary supply of iodine in the normal human individual is concerned, since the iodine of many common foods, as milk and sea foods, appears to be readily available to the organism. However, in patients whose iodine requirement may be greatly augmented by hyperactivity of the thyroid gland or by other pathologic conditions, the question of supplying iodine in its most utilizable form may become highly significant.

## EFFECTS OF HEAT ON THE HUMAN BODY

Consideration of the effects of heat falls into two natural divisions; namely, the acute results of encountering high temperatures for short periods, and the effects of residence in tropical climates. Drinker,<sup>1</sup> in a recent article, has discussed some of the physiologic aspects of encountering these two forms of heat. Sweat is an important element concerned in body response to high temperatures. Since sweat contains from 0.1 to 0.5 per cent of sodium chloride, a daily production of sweat of 7.5 liters, such as may occur under the influence of high temperatures, would mean a loss of approximately 22.5 Gm. of salt. Since the average normal excretion

of salt in the urine is only about 12 Gm. in twenty-four hours, such a depletion of body chlorides probably would initiate most important physiologic events. Under such circumstances, therefore, it would be necessary to restore the normal salt-water ratio as rapidly as possible. For this purpose, excess salt administered both orally and under the skin combined with milk by mouth usually furnishes an adequate supply of both essentials and aids in the prevention of heat cramps. In fact, as Drinker points out, the prevention of heat cramps is of greater importance than their treatment. Men at hard work under high temperatures must be in good physical condition. Alcohol and excess of all sorts must be avoided. A sodium chloride intake of at least 15 Gm. a day must be maintained. Some sort of adaptation appears to occur in physically competent men placed at work in high temperatures. Little is known of the nature of this acclimatization, but apparently men sweat more readily as they become accustomed to exposure to heat; also the sweat appears to contain a lower concentration of sodium chloride. Such conditions as "heat exhaustion" and "heat stroke" appear to be due to abnormal stimulation of heat production. Treatment of these disturbances consists in the use of cold packs or cold baths, salt solution under the skin, and water by mouth as soon as possible.

The slower and more subtle effects of prolonged residence in the tropics are of even more importance to man. The gradual deterioration in health which white persons experience constitutes the real problem. Deterioration is in fact the rule, and two years is probably the longest safe period for tropical residence. Furthermore, it is probable that the effects of tropical residence are worse in women and children than in men. The basal metabolism of individuals transferring from a temperate to a tropical region seems to undergo considerable individual variations. Thus, in one person's observations on himself, the basal metabolism began to fall within a few days after hot weather was encountered. It remained low until cooler weather was brought by trade winds, when it immediately rose to its previous level. In other instances, however, significant changes in basal metabolism were not noted. As a rule, a slight increase in body temperature is the rule on entering tropical climates. Height is apparently attained more readily than in temperate regions, and fatness is uncommon. A tall, thin type of person is perhaps best suited for tropical residence, having a maximum surface for heat loss in relation to body weight. Fertility appears to be reduced in the tropics, both sexes being affected. A slight decrease in pulse rate and in systolic blood pressure is the rule, but the changes are relatively insignificant. Respiration tends to decrease in rate, and the minute volume is somewhat higher. Alterations in blood volume, if any, need further detailed study. A slight alkalosis has been reported, particularly in persons leading a sedentary life in the tropics. Blood

sugar is apt to be low, and nonprotein nitrogen has been reported from northern Australia to be increased. A reduction of total phosphorus in the blood has also been reported. Red cells are slightly increased in number and white cells decreased, though in neither is the change important. Little is definitely established as to the effect on the ductless glands and nervous system. It is said that after about 3 years of age children tend to become weak and apathetic and that initiative and application become poor after the tenth year. In the case of adults, weakening of the will power with laziness and the gradual development of vicious habits are commonly noted. The latter observations, however, are invariably vague, and authorities are contradictory.

Drinker concludes that, in order to succeed in the tropics, white men must be willing to undergo discipline they would not subject themselves to in the north. The principles that should govern life in the tropics are simple and consist in moderate amounts of simple food, plenty of water, adequate salt intake, daily exercise, no alcohol and adequate sleep. This simple summation of the effects of long continued heat and the methods of combating it should serve as an admirable basis for present discussions and further investigation.

#### VITAMIN B<sub>1</sub> AND PYRUVATE METABOLISM

In the rapid development of our knowledge of the chemistry and physiology of the vitamins, definite chemical structures have already been assigned to a number of them. The symptoms of vitamin deficiencies have been established and in many instances the resulting pathologic condition has been largely clarified. Although the end results of vitamin deprivation are now fully described, the early alterations in the normal physiologic functions of the organism, occurring before gross pathologic changes become manifest, are quite obscure. As in many other studies of intermediary metabolism, the initial and final steps in the process are easier to elucidate than are the transformations that take place in the course of the development of symptoms of deficiency. Investigators are, however, actively looking into these difficult relationships. The studies have already produced data with respect to the possible relationship of vitamin B<sub>1</sub> to carbohydrate metabolism in general and, more specifically, to the transformations of two important intermediate catabolites of carbohydrate metabolism: lactic and pyruvic acids.

Investigations in the department of biochemistry at Oxford University demonstrated<sup>1</sup> that there is an increased amount of lactic acid in the brain of pigeons in the terminal stages of vitamin B<sub>1</sub> deficiency, as compared with the lactic acid content of the brain tissue of normal birds. A reaction<sup>2</sup> for pyruvic acid was

1. Kinnersley, W. H., and Peters, R. A.: *Biochem. J.* **23**:1126 (No. 5) 1929.

2. Peters, R. A., and Thompson, R. H. S.: *Biochem. J.* **28**:916 (No. 3) 1934.

observed in lactate solutions in which the diseased pigeon brain had respired *in vitro*. Furthermore, the addition of crystalline vitamin B<sub>1</sub> caused an extra uptake of oxygen and a disappearance of lactate and pyruvate from the incubating mass of tissue. These results led to the hypothesis that vitamin B<sub>1</sub> is indirectly concerned with the oxidative removal of lactate and pyruvate in the avian brain. It was suggested that the effect of the vitamin is indirect because of the wide variations of the data found for the ratio of extra oxygen uptake to pyruvic acid disappearing, when these values were compared to the calculated ratios. The results are striking for the reason that pyruvic acid has thus been demonstrated to be the first organic substance which disappears *in vitro* as the result of the action of vitamin B<sub>1</sub>. The observations are in harmony with an early suggestion that disorders observed in polyneuritis may be due to the accumulation of intermediate substances, arising from carbohydrate breakdown, which cannot be metabolized in the absence of the vitamin.

Sherman and Elvehjem,<sup>3</sup> at the University of Wisconsin, prepared for chicks a ration so low in vitamin B<sub>1</sub> that polyneuritis develops within two weeks. This makes available another type of test bird for studying the rôle of vitamin B<sub>1</sub> in the metabolism of pyruvic or lactic acid in brain tissue. The results of their tests are not entirely in agreement with those of the Oxford group. The Wisconsin investigators have found that there are no significant disturbances in lactate oxidation of brain tissue of avitaminous chicks. The heart tissue of these chicks showed a decreased rate of oxygen uptake in lactic acid and a decreased rate of removal of the acid. With the heart tissue, an increased oxygen uptake was produced by the addition of vitamin B<sub>1</sub>. The latter compound, however, was without effect on lactate oxidation by brain tissue. These discrepancies in results are not serious when it is recalled that only a short period was required for the development of the polyneuritis in the chicks, as compared to the thirty days required to produce head retractions in the pigeons. It may be that, in the more rapidly developing polyneuritis, disturbances in tissue metabolism may appear in the heart and possibly other organs before the demonstrable effects on the central nervous system are produced. When pyruvate serves as the substrate, the results of the two laboratories are in good agreement. In avitaminous brain tissue there is a decreased respiration in pyruvate substrate. The addition of crystalline vitamin B<sub>1</sub> brings back the lowered oxygen uptake to an almost normal level and increases the rate of pyruvate removal. Sherman and Elvehjem have also demonstrated that kidney tissue from normal and from polyneuritic chicks acts similarly with respect to pyruvic acid.

The *in vitro* evidence of the atypical metabolism of pyruvic acid in avitaminous pigeon and chick tissues has

led to the hypothesis that the syndrome of polyneuritis is directly caused by an accumulation of pyruvic acid. This idea now gains some support from a study of the metabolism of pyruvate in avitaminosis B<sub>1</sub> in the living animal. The Wisconsin workers<sup>4</sup> have followed the rate of removal of intravenously injected pyruvate from the blood of normal and of polyneuritic chicks. Pyruvate injected intravenously in normal chicks could not be significantly detected one minute after injections of amounts sufficient to produce a large theoretical increase in blood pyruvate. On the other hand injection of sodium pyruvate in polyneuritic chicks produced a sharp increase in blood pyruvate, which slowly returned to the normal level. These observations are consistent with the hypothesis that in polyneuritis there is a failure in the tissue metabolism of pyruvic acid. The possible relationships of this result to the gross pathologic changes developing in long sustained vitamin B<sub>1</sub> deficiency remain to be established.

## Current Comment

### BLOOD PHOSPHATASE IN DIAGNOSIS OF JAUNDICE

The significance of phosphatase in the blood has for some time been a subject of debate. Rothman and his co-workers<sup>1</sup> have recently reported a study of the blood-phosphatase based on all the cases of jaundice observed by them during the past three years and on a series of cases without jaundice and with none of the other pathologic states believed to influence phosphatase values. The cases of jaundice were classified in the orthodox manner under the heads of obstructive jaundice, hepatocellular or nonobstructive jaundice and hemolytic jaundice. The method of phosphatase determination employed by these investigators was a slight modification of Roberts' method. In many instances the phosphatase determinations were repeated at frequent intervals, and in most instances quantitative serum bilirubin determinations were done simultaneously. The phosphatase values in most of the cases of obstructive jaundice were found to have values of greater than 10 units, while in the nonobstructive cases the values were found to be 10 units or less. These investigators agree with others, notably Roberts, that a phosphatase value of 10 units may be considered the dividing line between cases of obstructive and nonobstructive jaundice. Furthermore, phosphatase determination seems to be of greater value than any other available test in differentiating between these two forms of jaundice. Hence it appears that the blood phosphatase reflects two mechanisms: that due to obstruction and that due to a more direct involvement of the liver parenchyma. When both of these disturbances are present, the extent of each can be roughly gaged by comparing the bilirubin with the phosphatase values.

## MEDICOLEGAL CASES: 1931-1935

Abstracts of medicolegal cases have been published weekly in *THE JOURNAL* since 1900. They reflect the many and varied medicolegal problems that often perplex the busy practitioner. They indicate as well the ways in which others have met, or failed to meet, difficult medicolegal situations. The interest that has been aroused by these abstracts has been shown by repeated requests from many physicians that they be made available in book form. An initial volume was published in 1932 containing the abstracts that appeared in *THE JOURNAL* during the calendar years 1926-1930 inclusive. Now a second volume, entitled "Medicolegal Cases: 1931-1935," will soon be ready for distribution. This second volume will embody abstracts that were published in *THE JOURNAL* from Jan. 1, 1931, to Dec. 31, 1935. It will comprise a table of cases, 813 pages of abstracts, and seventy-four pages devoted to a detailed, comprehensive index affording ready access to the many interesting points developed in the approximately 900 abstracts. The book will be bound, as was its predecessor, in durable library buckram, law book style. Physicians, lawyers and others interested in avoiding legal difficulties and in solving medicolegal problems when they arise will find this volume a useful and interesting addition to their reference libraries.

## Association News

### ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD NOV. 15 AND 16, 1936

DR. HOWARD FOX TO SUCCEED DR. WILLIAM ALLEN PUSEY  
ON EDITORIAL BOARD OF ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY

The resignation of Dr. William Allen Pusey from the Editorial Board of the *Archives of Dermatology and Syphilology*, to take effect on December 31, was accepted and the deep appreciation of the Board for the fine service he has rendered for so many years was expressed.

Dr. Howard Fox of New York was elected to succeed Dr. Pusey as editor in chief.

#### RESIGNATIONS FROM COUNCIL ON PHYSICAL THERAPY

The resignations of Dr. F. J. Gaenslen and Dr. George Miller MacKee from the Council on Physical Therapy, due to illness, were accepted. Dr. George Clinton Andrews of New York was elected to succeed Dr. MacKee. Dr. Gaenslen's successor will be announced later.

#### APPOINTMENTS

A standing committee of the Board of Trustees to study the problems of industrial medicine and a committee to determine the value of x-ray film with a paper base as a substitute for film with a gelatin base were appointed. The Board approved nominations submitted by the President for a committee to survey and study the problem of motor vehicle accidents and injuries therefrom and to report to the House of Delegates, in accordance with a resolution introduced in the House of Delegates at the Kansas City session. The composition of these committees will be announced when acceptances of the appointments have been received.

Dr. W. J. McConnell of New York was appointed to represent the American Medical Association on the Sectional Committee on Building Code Requirements and Ventilation of the American Standards Association; Dr. Edward Jackson of Denver, to succeed himself on the Sectional Committee on Standards of School Lighting, and Dr. Austin A. Hayden of

Chicago, Secretary of the Board of Trustees, to succeed Dr. Wendell C. Phillips (deceased) on the Committee on Sound Level Meters.

#### CHAIRMAN OF LOCAL COMMITTEE ON ARRANGEMENTS

The nomination of Dr. W. J. Carrington as chairman of the Local Committee on Arrangements for the 1937 session of the Association, to be held in Atlantic City, was confirmed.

#### SUBSTITUTION OF SUPPLEMENT TO JOURNAL FOR A. M. A. BULLETIN

The discontinuation of the publication of the *American Medical Association Bulletin* and the substitution therefor of a supplement to *THE JOURNAL* each week, to be devoted to organizational affairs, medical economics, the social aspects of medical practice and similar material, received approval.

#### ANNUAL REPORTS ON TYPHOID, DIPHTHERIA AND FOURTH OF JULY STATISTICS

The Board authorized continuation of the publication in *THE JOURNAL* of the typhoid and diphtheria statistics and the resumption of the publication of statistics of Fourth of July accidents.

#### CONFERENCE ON SYPHILIS

The Surgeon General of the United States Public Health Service appeared before the Board for a discussion of certain phases of the program of that service and expressed the desire to have the active cooperation of the medical profession, especially at this time, in connection with plans to be developed for the prevention and treatment of syphilis.

#### MISCELLANEOUS

Numerous other matters pertaining to the business and work of the Association were given full consideration.

#### COMMITTEES PREVIOUSLY APPOINTED

The composition of committees appointed at the meeting of the Board of Trustees in September is as follows:

Committee to Study Air Conditioning: Drs. William F. Petersen, Chicago; H. B. Williams, New York; Emery R. Hayhurst, Columbus, Ohio; Carey P. McCord, chairman, Detroit, and C. P. Yaglou, Boston.

Committee on Asphyxia: Drs. Paluel J. Flagg, New York; John S. Lundy, Rochester, Minn., and Thomas J. Vischer, Philadelphia.

Committee on Medicolegal Blood Grouping Tests: Drs. Karl Landsteiner, New York; Alexander S. Wiener, Brooklyn, and Ludvig Hektoen, Chicago.

Advisory Committee on Cosmetics of the Advertising Committee: Drs. C. Guy Lane, Boston; Joseph Jordan Eller, New York, and Francis E. Seneor, Chicago.

#### RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series, the thirty-second dramatized cooperative broadcast under the title *Your Health*, was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve American people in sickness and in health."

The program will go out on the Blue network instead of on the Red network, as originally announced.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each issue of *THE JOURNAL*. The topics and speakers for the next three programs are:

- December 8. Heredity and Disease. Morris Fishbein, M.D.
- December 15. Milk. W. W. Bauer, M.D.
- December 22. The Gift of Health. Morris Fishbein, M.D.

The time of the broadcast is Tuesday afternoon at 4 o'clock central standard time (5 o'clock eastern time, 3 o'clock mountain time, 2 o'clock Pacific time).

## NEW JERSEY

**Society News.**—Dr. Joseph H. Globus, New York, addressed the Academy of Medicine of Northern New Jersey, Newark, November 19, on "Intracranial Hemorrhage: Its Anatomical Forms and Some of Their Clinical Features."—Dr. Christian P. Segard, Leonia, addressed the Mercer County Medical Society at Trenton, October 14, on "Late Developments in the Field of Nutrition."—A symposium on "The Injection Treatment of Hemorrhoids" was presented at the meeting of the Passaic County Medical Society, Paterson, October 8, by Drs. Rudolph V. Gorsch, New York, and Carroll D. Smith, Paterson.—Dr. Charles F. Geschickter, Baltimore, and Henry F. Vaughan, Dr. P.H., Detroit, were guest speakers at the annual meeting of the New Jersey Health and Sanitary Association in New Brunswick, November 20, on cancer and on relations between physicians and health departments with regard to immunization, respectively.

**Revolutionary War Hospital Reconstructed.**—The National Park Service has reconstructed an eighteenth century army hospital as part of its educational exhibit in the Morristown Historical National Park, Morristown, N. J. It is in Jockey Hollow, the site of the Continental Army encampment during the winter of 1779-1780 and one of three units in the Morristown park. The building is considered to be a close reproduction of the original hospital and it is planned

Eighteenth century army hospital.

to furnish it with displays of medical instruments, medicines and other contemporary material or reproductions to give visitors a picture of Revolutionary medical practices. The Morristown Historical National Park was established by an act of Congress approved March 2, 1933. The three units are Washington's headquarters, which contains a large collection of Washingtoniana, much other material typical of the Revolutionary period, and a library of nearly 2,000 volumes on early American history; Fort Mifflin, redoubt constructed at Washington's order in April 1777, and the Jockey Hollow Encampment sites. The picture is reproduced by courtesy of the park officials at Morristown.

## NEW YORK

**Society News.**—Dr. J. Ivimey Dowling, Albany, addressed the Medical Society of the County of Albany, November 24, on "Sinus Surgery as Applied to the Eye and General Health."—Mr. Elvin R. Edwards, former district attorney of Nassau County, addressed the Medical Society of the County of Nassau, November 24, on "The Doctor and the Lawyer."

**State Industrial Physicians Meet.**—Dr. Willis C. Temple, Corning, was elected president of the New York State Society of Industrial Medicine at the sixteenth annual meeting in Schenectady, November 5. The speakers included Drs. David J. Kaliski, New York, on "Workmen's Compensation Law as Related to Medical Practice"; Fred W. Stewart, New York, "Relationship of Single Trauma to Malignant Tumors," and William Gayle Crutchfield, Richmond, Va., "Reduction of Fracture—Dislocation of the Cervical Spine with Skeletal Traction." A symposium on hernia was presented by Drs. Arthur F. Hirsch, New York, and Norman L. Higinbotham, New York, and William H. Stanton, Schenectady.

## New York City

**British Anatomist to Succeed Dr. Senior.**—Dr. Donald Sheehan, formerly demonstrator of anatomy, Victoria University of Manchester, Manchester, England, has been appointed professor of anatomy and director of the anatomic laboratories at New York University College of Medicine to succeed Dr. Harold Dickinson Senior, who retired in September. Dr. Sheehan, who will assume the position Sept. 1, 1937, received the degree of bachelor of medicine and surgery at Victoria University in 1929, doctor of medicine in 1932, and doctor of science on the basis of research on the anatomy of the autonomic nervous system in 1936.

**Society News.**—Drs. Leland S. McKittrick and Howard F. Root, Boston, addressed the Bronx County Medical Society, November 18, on recent progress in diabetic surgery and therapy, respectively.—At a meeting of the Bronx Gynecological and Obstetrical Society, November 23, the speakers were Drs. Samuel W. Boorstein and Sidney H. Freilich on "Restoring Function in Cases of Obstetrical Brachial Palsy" and Abraham B. Tamis, "Management of Secondary Amenorrhea."—Dr. David L. Satenstein addressed the Bronx Pathological Society, November 17, on "Dyskeratosis: Its Diagnostic and Prognostic Value in Grading Cancer of the Skin."

**Conné Medal Awarded to Dr. Van Slyke.**—The Philip A. Conné Gold Medal of the Chemists' Club of New York has been awarded to Donald Dexter Van Slyke, Ph.D., of the Rockefeller Institute for Medical Research, for "systematic and painstaking work of immense importance to clinical medicine," it was announced November 8. Dr. Van Slyke's work concerns chemistry and physiology of proteins and amino acids, enzyme action, methods of analysis of blood and gaseometric micro-analysis, respiratory and renal functions, diabetes and nephritis. A native of New York, Dr. Van Slyke was graduated from the University of Michigan in 1905 and received the degree of doctor of philosophy there in 1907. Yale University conferred on him the honorary degree of doctor of science in 1925.

**Research on Chronic Disease.**—The Research Division of Chronic Disease, established in the department of hospitals last year, has received grants amounting to \$7,875 from the research council of the department, supplementing its annual grant of \$25,000 from the board of estimate. The complete scientific personnel was recently announced by Dr. Sigismund S. Goldwater, commissioner of hospitals, as follows: Dr. David Seegal, research director; Forrest E. Kendall, Ph.D., Drs. Dickinson W. Richards Jr., Arthur J. Patek Jr., Kenneth B. Turner, Alfred Steiner and James S. Mansfield. Studies to be promoted include the mechanism of arteriosclerosis, pulmonary emphysema and fibrosis, cirrhosis of the liver and hypertension, the rôle of infection in chronic diseases with particular reference to chronic nephritis, and chronic arthritis. Officers of the research council for the current year are Mr. Marshall Field, Drs. Goldwater, John A. Hartwell and Bernard Sachs. The scientific advisory committee includes Drs. Alfred E. Cohn, Eugene L. Opie, Walter W. Palmer, Alphonse R. Dochez, Douglas Symmers and William H. Park. Dr. Martin H. Dawson is president of the medical board of the research division.

## OHIO

**Personal.**—Dr. William A. Welsh, Youngstown, won the championship trophy at the annual golf tournament of the Ohio State Medical Association at the annual meeting in Cleveland, October 6, with a score of 163 for thirty-six holes.

**District Meeting.**—The Ninth Council District of the Ohio State Medical Association held a meeting at Gallipolis, November 24, with the following speakers: Drs. Frank E. Stevenson, Cincinnati, on scarlet fever; William M. Millar, Cincinnati, diagnosis and treatment of cancer, and Charles A. Doan, Columbus, treatment of certain blood dyscrasias.

**Society News.**—Dr. Dudley M. Stewart, Toledo, addressed the Sandusky County Medical Society, Fremont, October 29, on "Orthopedic Problems in General Practice."—Dr. Wallace B. Taggart, Dayton, addressed the Darke County Medical Society, Greenville, November 20, on "Chronic Lung Infections in Children."—Dr. Esther B. Tietz of Longview State Hospital, Cincinnati, addressed the Butler County Medical Society, November 4, on "Paper Diagnosis of Psychoses."—Dr. Hiram B. Weiss, Cincinnati, addressed the Hempstead Academy of Medicine, November 9, on "Hypertension and Hypotension."

## OREGON

**University News.**—The departments of anatomy and otolaryngology at the University of Oregon Medical School, Portland, have received a grant of \$400 from the American Academy of Ophthalmology and Otolaryngology to continue research on diseases of the sinuses under the direction of Olof Larsell, Ph.D., and Dr. Ralph A. Fenton.

## PENNSYLVANIA

**Society News.**—Dr. Charles G. Strickland, Erie, addressed the Warren County Medical Society, November 16, on "Ovarian Tumors."—Dr. Charles L. Brown, Philadelphia, addressed the Bucks County Medical Society, November 11, on "Cardiac Arrhythmias—Their Clinical Symptoms." At this meeting the committee on public relations and medical economics was empowered to ask the county commissioners for \$6,000 for the care of the indigent for one year, this amount to include the

salary of a secretary to be under the control of the society. The committee was also empowered to ask for money to pay for hospitalization of the indigent.—Drs. William J. Daw, Forty Fort, and William Baurys, Nanticoke, addressed the Luzerne County Medical Society, Wilkes-Barre, on "Hypertrophy of the Prostate" and "Internal Urinary Antiseptics," respectively.—Dr. Austin C. Lynn, Philipsburg, among others, addressed the Clearfield County Medical Society in Philipsburg, November 12, on "Diseases of the Hand."

#### Philadelphia

**Dr. Müller Appointed Professor of Surgery.**—Dr. George P. Müller, formerly professor of clinical surgery at the University of Pennsylvania Graduate School of Medicine, has been appointed professor of surgery at Jefferson Medical College to succeed the late Dr. Edward J. Klopp. Dr. Müller, a graduate of the University of Pennsylvania, is surgeon to the Lankenau and Misericordia hospitals. He is a member of the board of regents of the American College of Surgeons, a member of the Philadelphia College of Physicians and a past president of the Philadelphia County Medical Society.

**Testimonial to Dr. Strittmatter.**—One hundred and twenty-five friends attended a dinner in honor of Dr. Isidor P. Strittmatter, November 5, at the Union League of Philadelphia. Dr. Louis H. Clerf was toastmaster. A souvenir book bearing the signatures of the guests was presented to Dr. Strittmatter. Among the speakers were Drs. Wilmer Krusen, Henry D. Jump, Francis A. Faught and Ross V. Patterson. Dr. Strittmatter, who is 76 years old, graduated from Jefferson Medical College in 1881. In 1923 he established the Strittmatter Award to be given to the physician presenting to the Philadelphia County Medical Society the most valuable contribution to the healing art in any given year; it was awarded for the first time in 1933. Dr. Strittmatter was president of the Philadelphia County society in 1928.

**Three Day Cancer Program.**—Several organizations joined in presenting a three day cancer program in Philadelphia November 30-December 2. The Pennsylvania Association of Tumor Clinics held a meeting November 30 at Lankenau Hospital, with surgical clinics and round table discussions in the x-ray department and the pathology laboratories of the hospital. The next two days were devoted to a cancer forum for the general public presented by the Women's Auxiliary of the Lankenau Hospital Research Institute for the Promotion of Cancer Research. Among the speakers were:

Dr. Francis Carter Wood, New York, Stepping Stones in Cancer Knowledge.  
Dr. James J. Durrett, chief of the drug division, Food and Drug Administration, Washington, "Quacks" and Their Methods.  
Mr. H. J. Klein, Metropolitan Life Insurance Company, New York, Insurance Companies in Relation to Cancer.  
Clarence C. Little, Sc.D., Bar Harbor, Maine, Cancer Control.  
Dr. Madge T. Macklin, London, Ont., The Brighter Side of Cancer.  
Dr. Victor G. Heiser, New York, Cancer in Primitive Peoples.

The Philadelphia County Medical Society presented a symposium on malignant tumors, December 2, with Dr. Madge T. Macklin as a speaker on the hereditary background as one of the major causes of malignancy and Dr. Joseph McFarland, Philadelphia, on the environmental background. The sponsoring agencies were the American Society for the Control of Cancer, the Cancer Commission of the Medical Society of the State of Pennsylvania, the committee on cancer control of the Philadelphia County Medical Society, the State Federation of Pennsylvania Women and the Philadelphia Federation of Women's Clubs and Allied Organizations.

#### Pittsburgh

**Research on Optical Glass.**—Investigations of the chemistry and physics of glass surfaces to aid in the development of scientific apparatus and ophthalmic instruments is under way at Mellon Institute of Industrial Research under the auspices of the Bausch and Lomb Optical Company of Rochester, N. Y. Frank L. Jones, Ph.D., a member of the staff since 1931, will be in charge of the new investigations, which will be concerned with the effects of environmental factors on the durability of the glass used in optical instruments.

#### TEXAS

**Clinics at Fort Worth.**—The Tarrant County Medical Society sponsored the Fort Worth Medical and Surgical Clinics, October 6, with Drs. William L. Bonham, Leo J. Starry and Minard F. Jacobs, all of Oklahoma City, as guest speakers. Clinics were held at Baptist, Cook and Harris hospitals and dry clinics at the Medical Arts Building. Dr. John E. Daly was chairman of the committee in charge of arrangements.

**Personal.**—Dr. Alwin M. Clarkson, Dallas, has been appointed epidemiologist to the state department of health to succeed Dr. Charles D. Reece, Austin, who resigned.—Dr. Austin E. Hill, Dallas, has been appointed health officer of Smith County, and Dr. Lyman T. Cox, El Paso, of the Winkler County unit.

**State Surgical Meeting.**—Drs. John de J. Pemberton, Rochester, Minn., and Edward W. A. Ochsner, New Orleans, were guest speakers at the semiannual meeting of the Texas Surgical Society in Dallas, October 5-6. Dr. Pemberton spoke on "Surgery of the Colon" and Dr. Ochsner on "Prevention of the Reformation of Peritoneal Adhesions by Papain: A Clinical Consideration." Dr. Charles C. Green, Houston, was elected president.

**University News.**—Dr. Percival A. Duff, formerly of Los Angeles, has been appointed assistant professor of pathology at the University of Texas School of Medicine, Galveston, and Dr. Truman J. Blocker Jr. has been appointed associate professor of surgical pathology. Dr. Clarence S. Sykes has been promoted to the rank of associate professor of ophthalmology. Newspapers recently reported that Dr. Paul A. Woodward has resigned as associate professor of medicine and Dr. Loyd W. Sheekles Jr. has been promoted to be assistant professor of medicine. At the opening session of the fall term October 1 an address was made by Dr. Seth M. Morris, professor of ophthalmology, who is the only member of the original faculty of the school who has remained in continuous service. Dr. Morris will retire at the end of this year.

#### WISCONSIN

**Society News.**—At a meeting of the Milwaukee Society of Clinical Surgery, November 24, the speakers were Drs. Claude S. Beck, Cleveland, on "Surgery of the Heart and Pericardium"; David A. Cleveland, Milwaukee, "Early Diagnosis of Brain Tumors," and Hugh McKenna, Chicago, "Treatment of Fractures of the Neck of the Femur."—Drs. Fred H. Albee, New York, and Francis D. Murphy addressed the Medical Society of Milwaukee County, November 13, on "Bone Carpentry" and "The Use of Insulin Protamine in the Treatment of Diabetes" respectively.—At a meeting of the Milwaukee Oto-Ophthalmic Society, November 10, the speakers were Drs. Robert Sonnenschein, Chicago, on "Reflexes or Referred Signs and Symptoms of Diseases of the Nose, Throat and Ear"; Samuel J. Pearlman, Chicago, "Modern Conceptions of Therapy of Malignant Growths of the Pharynx and Larynx," and Samuel Salinger, "Treatment of Injuries to the Face."—Drs. Charles W. Mayo and Edwin J. Kepler, Rochester, Minn., addressed the Eau Claire-Dunn-Pepin Counties Medical Society, in Eau Claire, October 26, on "Surgery of the Colon" and "Endocrinology" respectively.

#### GENERAL

**Unauthorized Subscription Agent.**—The *Archives of Physical Therapy* reports that a Mr. H. Harvey of Toronto, who was authorized to represent that journal several months ago, is no longer an accredited agent. Harvey at first reported having taken some subscriptions but has not been heard from for some months. The American Congress of Physical Therapy has had complaints from physicians who have subscribed but have not received their journals.

**Health of Students Studied.**—The American Youth Commission is sponsoring a survey to be made of student health in sixty representative American colleges and universities, it is announced. Dr. Harold S. Diehl, dean of medical sciences, University of Minnesota Medical School, and Dr. Charles E. Shepard, associate professor of hygiene and physical education, Stanford University School of Medicine, will make the survey, and federal aid students will be employed to assist on the project. The youth commission is a subsidiary of the American Council on Education, Washington, D. C.

**Examinations in Otolaryngology.**—The American Board of Otolaryngology will hold an examination in Philadelphia June 7-8, 1937, during the annual session of the American Medical Association in Atlantic City. Prospective applicants for certificates should obtain blanks from the secretary of the board, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, Neb. In an examination prior to the annual meeting of the American Academy of Ophthalmology and Otolaryngology in New York in September, 120 candidates were examined and 103 were certified.

**Physicians Paid with Counterfeit Money.**—Search is being made for a man who has been victimizing physicians in New York City. His procedure is to request a physical examination, in payment of which he gives a counterfeit \$20

bill. Physicians are asked to note carefully the serial numbers of bills coming into their possession, as the counterfeit ones are light in color and somewhat irregular in impression and alignment. The swindler is described as being short, heavy set, 5 feet 8 inches tall, weighing about 212 pounds, and about 39 years of age, with black hair and brown eyes. He is said to speak with a pronounced Greek accent and has been using the name of George Alexander. Physicians are asked to notify the nearest police officer.

**Society News.**—Dr. Fletcher H. Colby, Boston, was chosen president of the New England Branch of the American Urological Association at its meeting in Boston, November 12, and Dr. George C. Prather, Boston, secretary.—The American Academy of Tuberculosis Physicians will meet in Atlantic City, June 7-8, 1937. Dr. Charles O. Giese, Colorado Springs, is president, and Dr. Arnold Minnig, Denver, is secretary.—Dr. Frank K. Boland, Atlanta, was elected president of the Southern Medical Association at its annual meeting in Baltimore, November 18. Drs. Sydney R. Miller, Baltimore, and Leander A. Riely, Oklahoma City, were elected vice presidents and Mr. C. P. Loran, Birmingham, was appointed secretary and general manager for a term of five years.

**News of Epidemics.**—Schools in Tulsa, Okla., were closed November 2 and those of Tulsa County a week later because of an outbreak of infantile paralysis. In the three weeks that preceded November 2, forty cases had developed in Tulsa; only seventeen cases had occurred in the city since 1928.—Thirteen persons were ill of typhoid in Edna, Pa., a mining town in Westmoreland County, November 12; the infection was traced to a spring and two wells. A spring was blamed as the source of infection in an outbreak affecting eleven persons at Eldersville, Pa., another mining community.—Schools were closed in Gibsonburg, Ohio, November 5, after thirty-seven cases of scarlet fever were reported. Schools at Chebanse, Ill., were closed November 2 because of an outbreak there. The state health department of Minnesota reported 292 cases of scarlet fever during October.

**Meeting of Western Surgical Association.**—The forty-sixth annual meeting of the Western Surgical Association will be held at the Hotel Muehlebach, Kansas City, Mo., December 11-12. Other speakers will include:

- Dr. Warren H. Cole, Chicago, Pneumococcus Peritonitis.
- Dr. Waltman Walters, Rochester, Minn., Should Gastric Resection Be Done for Duodenal Ulcer?
- Dr. Verne C. Hunt, Los Angeles, Benign Tumors of the Stomach.
- Dr. William E. Gallie, Toronto, Canada, Further Experiences with the Transplantation of Tendon and Fascia.
- Dr. H. Winnett Orr, Lincoln, Neb., A Special Surgical Procedure and the Orthopedic After-Care in Spina Bifida.
- Dr. George M. Curtis, Columbus, Ohio, The Surgical Significance of the Accessory Spleen.
- Dr. Charles L. Patton, Springfield, Ill., Hepatic Duct Strictures.

The annual dinner of the association will be held Friday evening December 11. Dr. Thomas G. Orr, Kansas City, will deliver the presidential address on "An Incision for Complete Breast Amputation," Saturday morning.

**The Woman's Auxiliary.**—The October News Letter of the Woman's Auxiliary of the American Medical Association reports the activities and future plans of various state auxiliaries. The Illinois auxiliary plans to assist the legislative committee of the Illinois State Medical Society during the meeting of the legislature which opens in January. Among this year's objectives for Illinois are building up a clientele for periodic health examinations, building an audience of lay followers for radio programs of the state society and the American Medical Association, keeping in touch with health material in lay publications, and cooperation with other organizations for promotion of health education. The New York auxiliary was organized in March and now has six county units; the new group helped to defeat a chiropractic bill in the last legislature. West Virginia members are compiling a history of the West Virginia State Medical Association and each county plans to make a study of some topic of medical research for the library of the Southern Medical Auxiliary. This auxiliary will sponsor an exhibit of doctors' hobbies at the 1937 convention. Georgia's auxiliary lays its chief emphasis on its student loan fund to educate children of Georgia physicians in Georgia medical schools. Among other activities, it also presents a health education program in cooperation with the Medical Association of Georgia and observes "Doctor's Day" March 30 each year. The aims of the Kansas auxiliary for the year include presentation of health education programs, health activities in cooperation with other organizations, and study of legislation concerning medicine. At the recent annual meeting of the Virginia auxiliary it was decided that the group should undertake the maintenance of a bed in a tuberculosis sanatorium for the use of needy physicians or their dependents.

#### The British Medical Association and the Nostrum Evil

In spite of efforts to check the nostrum evil, it continues unabated. The press is full of more or less fraudulent advertisements of preparations that will cure all sorts of diseases. Highly respectable journals are no exception and the religious press seems to be among the worst offenders. Perhaps the vendors select it because there are people foolish enough to suppose that an advertisement in a religious publication is some sort of guaranty of respectability. For some years the British Medical Association has tried to grapple with the evil. During the years 1906 to 1909 it published analyses of secret remedies, which were made by the authority of the council. These were afterward collected and published in two books entitled "Secret Remedies" and "More Secret Remedies." These had extensive sale, though several of the more popular daily and Sunday newspapers refused to accept advertisements of the books, evidently because nostrums were extensively advertised in them. The analyses revealed to the public for the first time the worthless nature and trifling cost of many of the vaunted cures. Some of the vendors were audacious enough to turn the exposure to account by offering their preparations for sale as "according to the formula of the British Medical Association." They thus pretended that they were acting under the authority of the association. One man actually opened a "B. M. A. Store." The association was involved in considerable expense and litigation in stopping this unauthorized use of its name.

The association's hope that the government would take the matter up was realized when a select committee was appointed by parliament to inquire into the sale of "patent" and proprietary medicines. The association was invited to give evidence. It recommended that: 1. On every packet of a nostrum offered for sale the name and quantity of each of its constituents should be given. 2. The label should constitute a warranty, and false description should be made an offense. 3. The provisions of the Food and Drugs Act should apply to proprietary medicines. The committee made a number of important recommendations. A department of state should be established for dealing with the advertising and sale of "patent medicines." There should be a register of their manufacturers, proprietors and importers and a complete statement of their ingredients and proportions, and the therapeutic claims made should be supplied. The advertisement and sale of cures for cancer, consumption, deafness, diabetes, paralysis, epilepsy, locomotor ataxia and rupture (without appliance) should be prohibited. It should be illegal to invite sufferers from any ailment to correspond with the vender of a remedy or to use fictitious testimonials. These recommendations were warmly approved by the British Medical Association, but the outbreak of the great war prevented anything further being done. After the war the association endeavored to secure legislation and helped in the drafting of two bills, which were unsuccessful. The failure of a bill that was made moderate so as to secure the support of newspaper and advertising associations and representatives of the drug trade was reported in *THE JOURNAL*, May 23, page 1829. It would have prevented only the worst forms of unscrupulous advertising, on the lines of the recommendations of the select committee, but it was "talked out." This deplorable result was brought about by misleading propaganda and by exploiting the suspicion of a section of the public that the medical profession in supporting the bill was actuated by selfish motives.

It is now stated in the *British Medical Journal* that the medical secretary of the association is asked almost daily for

information concerning the chemical composition and therapeutic activity of one or other of the numerous nostrums that excite the hopeful curiosity of patients. Unfortunately the particulars required are often not available. There is great difficulty in providing adequate information on the whole class of secret remedies, but the possibility of arranging for chemical analyses in special cases is under consideration. The association is also trying to secure the elimination from the press of advertisements that are obviously fraudulent or misleading. Although many newspaper proprietors are loath to take action that would diminish their income, considerable success has been achieved with the proprietors of the higher class newspapers and periodicals. The association's attention was drawn to objectionable advertisements of "patent medicines" in church magazines. Certain religious organizations were approached, and the Guild of St. Luke agreed to issue to clergymen of the Church of England a pamphlet on the harmful effects of "patent medicines" and a warning against their advertisement in church magazines. The association has also been disturbed by advertisement of "patent medicines" in some government publications, such as books of stamps, because the nature of the medium is liable to suggest that the products advertised have some sort of government approval. A promise has been obtained that remedies for certain diseases shall not be advertised, but not all undesirable advertisements are being refused. The association would like to secure control of the sale of "patent medicines" such as now exists in Canada.

#### The Association for the Advancement of Science

At the annual meeting of the British Association for the Advancement of Science, several papers of special interest to physicians were read.

#### THE MECHANISM OF EVOLUTION

Dr. Julian Huxley took for the subject of his presidential address "Natural Selection and Evolutionary Progress." He pointed out that three distinct problems were involved in evolution—the origin of species, the origin of adaptations and the origin and maintenance of long range evolutionary trends. As to the mechanism of evolution, the Lamarckian hypothesis might be neglected for lack of positive evidence and the atrogenetic view disregarded until it was seen how far the theory of natural selection would go. Natural selection was the only hypothesis (apart from creationist or mystical-vitalist ones) that would help account for any adaptive character the origin of which involved several separate steps. After a period in which Mendelism and natural selection appeared to be antagonistic, progress in genetics, aided by mathematical analysis, was once more favoring a selectionist interpretation. It was now realized that mutations might be of any extent, so that, by selection of very small ones, evolution might be very gradual. Further, it was recently discovered that the effects of mutation might be radically altered according to what other genes were present. Thus, through the selection of the appropriate combination of modifying genes, evolution might be made still more continuous.

The origin of species took place in several distinct ways. The chief three might be called the divergent, the convergent and the reticulate. Divergence was usually consequent on the isolation, either geographic or physiologic, of two stocks and was always gradual. Convergent species-formation was so far known only in plants; it arose suddenly by chromosome doubling after hybridization. In reticulate species formation, diverging stocks were crossed and produced new combinations, so that the lines of ancestry formed a network. One type was found in such plants as willows and roses, another in the human species. Analysis revealed the curious fact that, so far as one could be sure of a negative proposition, the course of evolution up to its present phase of conceptual thought and speech could

not have occurred along any other line. It could have been realized only in a vertebrate, among vertebrates only in a mammal, and in mammals only in one with a long arboreal past and the characteristic of producing only one offspring at birth.

#### THE DIET OF THE PEOPLE

Sir John Orr said that an international committee of physiologists had reported that a daily supply of  $1\frac{3}{4}$  pints of milk, one-fourth pound of meat, fish or poultry, one egg, an ounce of cheese, half a pound of potatoes, one-fourth pound of vegetables and legumes would provide all the proteins, minerals and vitamins which a mother needed. When this diet and a corresponding one for children were compared with the diet common in this country, the protective foods were hopelessly inadequate in the lowest income group. As income rose the diet approached closer and closer to the optimal standard, but the diet of nearly half the population was below this. Sooner or later an optimal diet would be available for everybody. A committee had recommended measures to bring milk consumption up to a level roughly the same as that recommended by the international committee. The present consumption of milk was less than half a pint per head daily. The average consumption of eggs should be raised from four to seven a head weekly. The greatest shortage was in fruit and vegetables.

#### Surgical Treatment of Pulmonary Tuberculosis

Almost the entire June 30 and July 7 sessions of the Académie de médecine were devoted to a discussion of the surgical treatment of pulmonary tuberculosis by phthisiologists and surgeons well qualified in this rapidly developing field.

The first paper was by Prof. Emile Sergent and two of his associates, Pruvost and Mignot, who emphasized the necessity of close medicosurgical cooperation. They stated that an artificial pneumothorax offered the most effective means of assuring immobilization of the lung and that surgery is indicated only when collapse therapy is not applicable, after having been given a preliminary trial. Operation also is indicated when adhesions form following an insufflation and when the lesion for which the pneumothorax has been done is still active. In reviewing statistics, one must bear in mind that not only operative but also therapeutic results must be considered.

The division of bands binding the lung to the chest wall, diaphragm or mediastinum was first proposed by Jacobus as aiding an artificial pneumothorax by permitting the lung to collapse. It is not applicable to the extensive partial symphysis that may exist from the beginning of the pneumothorax treatment or be secondary to the latter. The best methods of diagnosis of the existence and location of true bands are radiography and pleuroscopy. In unilateral pneumothorax, the operative division of a band is indicated if it keeps a diseased lobe from collapsing and the expectoration is positive for tubercle bacilli. In bilateral pneumothorax cases, division of bands that interfere with the collapse of the lungs is indispensable. The contraindications to the division of such bands are activity of the pulmonary lesion as well as acute or chronic pleurisy. One should never operate too soon because of the danger of pleural complications and because of the fact that the bands are often very short and too vascular. As additional reasons for not operating too early on bands are the difficulty of compressing the lesions and the possibility that there may be secondary localizations. On the other hand, division of bands should be carried out very early in cases of bilateral pneumothorax in order to have a rapid collapse of the lungs. Division of bands may be encountered as an emergency measure in cases of severe

hemoptysis, extension of a cavity beneath the pneumothorax, rapid symphysis in a recent pneumothorax, certain lung perforations or pregnancy.

As to operations on the phrenic nerve, some have proposed as a routine to do a phrenicectomy following an unsuccessful collapse therapy before attempting a thoracoplasty. Now, one cannot regard indifferently a more or less definite paralysis of the diaphragm and thus diminish the value of the base of the lung when the latter is normal and thoracoplasty can be done later.

A careful radioscopy should precede a phrenicectomy, because a cavity in the central part of the upper lobe, relatively isolated and mobile, will probably not be influenced by such an operation. On the other hand, a cavity in the lower lobe that is constantly being drawn downward during inspiration will be favorably influenced by a phrenicectomy. To be successful, a considerable length of the phrenic should be removed and, if the paralysis is insufficient, the subclavian nerve must also be resected. Simple division, crushing or alcoholization of the phrenic nerve is followed by a paralysis, which may last from a few months to one or two years. Such temporary operations are reserved by the authors for such cases in which a thoracoplasty will probably be done later or the lesion although active tends to become stabilized and a thoracoplasty can probably be done a little later. The cases in which operations on the phrenic nerve promise favorable results are recent well localized lesions and nonencysted recent solitary cavities surrounded by parenchyma that is but little infiltrated. Apicolysis finds a limited field. It is indicated in quite small circumscribed relatively dry lesions presenting a tendency toward spontaneous retraction. Such lesions are frequently found in the apexes (supraclavicular regions) surrounded by normal parenchyma in patients whose general condition is a contraindication to a more extensive procedure. It can be employed also in association with other measures to collapse the lung.

Thoracoplasty should never be considered unless the lesions are unilateral and have not been active for from twelve to eighteen months, the patient is afebrile or nearly so, and the heart, which often is involved in chronic forms of tuberculosis, is in good condition. Thoracoplasty is to be avoided in destructive, caseating, active tuberculosis and employed only in cases in which the healing process is already manifested by the limitation of cavities and retractile sclerosis. A sanatorium should be one's first choice as the place in which thoracoplasty is to be performed. The most favorable cases are those in which the cavity is of moderate size, located rather near the surface and easy to collapse without much damage to the adjacent lung. The larger and more deeply seated the lesions, the more doubtful the result. It is a question whether one should attempt a thoracoplasty when sanatorium treatment has not improved the general condition, when there are remittent rises of temperatures, and when the lesions are not yet well localized. This holds also for those with large cavities with much secretion and emptying poorly, and for patients in whom the opposite lung is still under suspicion or at least still active. Old pneumothorax or oleothorax cases complicated by empyema and perforation can be greatly improved by thoracoplasty, provided the opposite lung is intact, the general condition is good and a preliminary pleurotomy is carried out.

The second paper was by Leon Berard of Lyons, who agreed with Sargent and his associates that, aside from cases of severe hemoptyses which persisted in spite of all treatment, thoracoplasty should be done only for inactive pulmonary lesions without pleural complications and preferably for lesions with a tendency to sclerosis, or with small cavities. The operation is indicated in only about 5 to 10 per cent of all cases. The number of ribs and the extent of each to be resected vary with the individual case. The immediate postoperative mortality has been reduced to from 4 to 8 per cent but neverthe-

less the later pulmonary complications cause it to rise during the first four months to 15 per cent. The mortality in sanatoriums where the patients have been well observed and prepared is only 10 to 12 per cent and the favorable end result as high as from 70 to 80 per cent, whereas in city hospitals the mortality rises to from 25 to 30 per cent and the favorable end results drop to from 50 to 60 per cent. This difference is due to the fact that hospital patients have not been given the preparatory rest and food which a sanatorium treatment gives.

The last paper of the June 30 meeting was by Robert Monod, a Paris surgeon who has had a large experience in resections of the lung. He raised the question whether intrapleural procedures should not be considered in cases in which pneumothorax and thoracoplasty have failed. In some cases partial resection of a lobe, even lobectomy or pneumectomy, might be seriously considered in view of recent more favorable results in nontuberculous conditions of the lung. One encounters solitary cavities of tuberculous origin well isolated by a fibrous shell of tissue from the adjacent normal parenchyma. Lobectomy hence could be justified in the following special cases: 1. Persistence or tendency to enlargement of a cavity in a collapsed lobe in which reexpansion as the result of a former thoracoplasty is no longer possible. 2. Persistence of a cavity the obliteration of which has not followed several thoracoplasties.

The discussion was continued at the July 7 meeting of the Académie de médecine by other surgeons who have had a large experience in this special field. Bernou and Fruchaud of Lyons gave the technic of partial thoracoplasty for lesions involving the pulmonary apexes. Such an operation is followed by an ample collapse of the lung and the operative mortality is very low, whereas rib resections that are too extensive in either a vertical or a horizontal manner are often followed by a very high mortality, owing to the sudden emptying of a septic pulmonary parenchyma or to serious disturbances of the thoracic equilibrium (mediastinal displacement with its action on the large vessels and opposite lung). This is true of thoracoplasties involving the first, fourth, fifth and sixth ribs at one sitting, as well as resections of the same ribs that extend very far anteriorly, if done at a single sitting. On the other hand, it is a mistake to divide operative intervention into too many steps or sittings, because in the intervals too much induration and ossification of the chest wall take place, and it is especially to be noted that the pulmonary collapse resulting from too many sittings is not very satisfactory. Every operation is followed by a rise of temperature and lighting up of tuberculous lesions, which exhaust the patient.

The second paper was by the thoracic surgeon A. Maurer and his associate Rolland on the real value of thoracoplasty. In the early period, eleven or twelve ribs were resected with a resultant high mortality rate. Maurer was one of the first, during a second period, to point out that a larger portion of a rib should be removed, especially in the apical region, where the entire first and 15 to 18 cm. of the second and third ribs respectively were resected. Up to April 1935 the plan was to operate in several sittings on lesions that were quiescent, attack only one side, and individualize for each case. Up to that date only subperiosteal resections were done, but the rapid formation of new bone necessitated making the intervals between operations as short as possible. For some time Schoemaker has proposed destruction of the periosteum with solution of formaldehyde to overcome these new bone formations. A little later, Maurer substituted complete removal of the periosteum. Since this procedure has been employed by the authors, one can lengthen the intervals between sittings and thus select a favorable time, so that 518 patients have been operated in 1,342 sittings. The operative mortality has been very low

(3 per cent) even in public hospital cases. There have been 80 per cent good end results in sanatorium cases and 55 per cent in public hospital services.

Prof. E. Rist, phthisiologist, spoke on the indications for phrenicectomy. He said that the value of operations for the temporary or permanent exclusion of the action of the phrenic nerve had perhaps at times been exaggerated but, on the other hand, they had been discredited to an extent that was not justified. These operations occupy today a place that is by no means negligible. It was observed in the early period that a simple phrenicectomy was followed by a rapid regeneration of the nerve and that, as a result, complete paralysis of the diaphragm failed to follow. The classic procedure at present is to remove about 12 cm. or more of the nerve in order to prevent regeneration. In addition, the subclavian nerve and scalenus muscles are also divided. Cordey and Philardeau have substituted alcoholization of the nerve to secure a temporary paralysis of the nerve and to perform, if necessary, a phrenicectomy later. In fact, such an alcoholization has been followed in some cases by permanent paralysis, and it has been found that a regeneration may follow an exeresis of the nerve.

All present-day collapsotherapy measures are based on a theoretical conception of pathologic physiology, but the results have not confirmed such a conception; hence empiricism plays an important part in all collapsotherapy procedures. This is as true of artificial pneumothorax as of thoracoplasty, and incomparably so of artificially produced paralysis of the phrenic nerve. The primary hypothesis was that section or exeresis of the phrenic nerve on the affected side would result in immobilization of the corresponding half of the diaphragm in a marked expiratory position and subsequent reduction in volume of the lung, the lower lobe of which would be immobilized. Thus, in cases in which pneumothorax became impossible to carry out because of pleural adhesions, an incomplete collapse could be obtained by phrenicectomy. Experience, however, has shown that, after the latter, an incomplete immobilization resulted because of paradoxical movements and radioseopy revealed that the paralyzed diaphragm moved in a direction opposite to that of the normal, the muscle rising during inspiration and descending during expiration. This inversion of the normal rise and fall is the most reliable radioscopic evidence of a paralysis of the diaphragm, whereas normal movements show that the motor innervation of the diaphragm has undergone restitution.

Furthermore, there is no parallelism between the reduction of volume of the lung and the efficacy of phrenicectomy. One can observe that tuberculous lesions heal in an incredible manner when the diaphragm has risen to only an insignificant degree. On the other hand, marked ascension of the diaphragm may not have any therapeutic influence on the pulmonary lesions. A priori, the only lesions that can be benefited are those in the lower lobe near the diaphragm, and it was found clinically, at first, that remarkably favorable results followed a phrenico-exeresis. The upper lobe is but little influenced by the inspiratory lowering of the diaphragm. Further experience, however, has demonstrated that apical lesions cicatrize and disappear at times soon after phrenico-exeresis; hence the indications for this operation are by no means limited to lesions at the base of the lung. The truth of the matter, according to Rist, is that our knowledge as to what is accomplished when the phrenic nerve is sectioned is still imperfect. It is possible that such an operation has an influence on the unstriated muscle fibers of the bronchi and of the parenchyma itself. Phrenicectomy yields the best results, however, in lesions situated near the base of the lung. Some phthisiologists (as Morin of Leysin) have been so well satisfied with phrenicectomy in apical lesions that they prefer it to artificial pneumothorax in such patients. Rist believes that the latter method

of collapse should be first given a trial because a phrenicectomy can always be done later, whereas the reverse is not true, because of the pleural adhesions that may follow an unsuccessful phrenicectomy, rendering an artificial pneumothorax impossible. Hence phrenicectomy is indicated only if it is impossible to collapse the lung by artificial pneumothorax.

Thoracoplasty should be attempted only under the most favorable condition, that is, when there is no longer any fever, the general condition is good, and suspected lesions in the opposite lung show evidence of inactivity. In such cases, during the waiting period, one may employ, as a useful preparatory measure, an alcoholization in order to obtain a temporary paralysis of the phrenic nerve. Even the permanent paralysis after a phrenicectomy is compensated for to a great extent by the lower intercostal and similar muscles. In the present state of development of collapsotherapy, phrenicectomy should not be discarded. Although of less value than artificial pneumothorax, it replaces the latter when it is a failure because of pleural adhesions. In cases in which thoracoplasty is impossible, the only available procedure is phrenicectomy, but the latter has its limits, which one must respect.

## BERLIN

(From Our Regular Correspondent)

Oct. 5, 1936.

### The Convention of Pediatricians

This year's convention of the German Pediatric Society was held at Würzburg. Professor Rietschel, the chairman, included in his address of welcome certain remarks that reflect the present-day trend in Germany. He raised the question of whether the pediatrician is truly a specializing physician in the strict sense of the term. A positive development, he said, has taken place; the actively practicing family physician is now so well trained in pediatrics that the services of the specialist in children's diseases, at least in the small and medium sized towns, may not be necessary. However, it may be supposed that pediatrics occupies as much a place in the education of the medical student as internal medicine.

The first major topic was "Antitoxie and Bacterial Serums." Gundel of Berlin emphasized that serotherapy is a biologic method in the truest sense of the word. Serotherapy still remains of indubitable fundamental worth (despite the fact that skeptical voices are raised in present-day Germany).

Speaking as a clinical pediatrician, Kleinschmidt of Cologne submitted a carefully formulated discussion based on his experimental and clinical investigation. He mentioned the many fruitless attempts, the many disappointed hopes, of the last ten years but declared that nevertheless restricted utilization of specific serums had become firmly established by experimentation. In this statement he struck at one of the weightiest principles of so-called Nature Medicine. Since it has been proved that the formation of antitoxin cannot be considered the curative factor in diphtheria, Kleinschmidt has for a long time been of the opinion that it is the nonspecific defense mechanisms of the organism that overcome the disease. The diminished effectiveness of antitoxin is particularly apt to manifest itself in cases of so-called toxic diphtheria and this is apparently due to hypersensitivity to toxin. Nevertheless the early injection of serum must not be discontinued for the present at least. The effectiveness of antitetanic serum is incontestable. Administration of antiscarlatinal serum is many times indicated. It apparently works in this way, however: that it alters the reaction of the organism against the pathogenic agent. Kleinschmidt questions the prophylactic action. Antidysenteric serum is of importance as antitoxic Shiga-Kruse serum; otherwise its effect is frequently only nonspecific. Administration of anticolon bacillary serum has not been proved superior to other measures in the diarrhea of

nurslings. The use of antipertussis serum has been unsatisfactory. The mortality from epidemic meningitis has not to date been definitely reduced through serotherapy. The outlook for success with type-specific serums is not great. Type I monovalent antipneumococcus serum is effective in lobar pneumonia and its prognosis in children is of itself good; the other type serum has to date been unproductive of success. Kleinschmidt closed his discussion with a statement the truth of which must be conceded by all critics: There are, he said, a whole group of precise indications for the application of specific serums, and no physician, if such indication is present, has the right to withhold from his patients the specific protective and curative serum. The significance of the organism's natural defense mechanisms and the importance of their influence should be fully recognized.

Schmidt-Burbach of Dessau then gave a report on comparative experimentation with various antidiphtheric inoculation serums. The best immunizing effect is produced by precipitate vaccine, alum-toxoid in particular. The Anhalt Serum Institute at Dessau now prepares an alum toxoid that contains 95 protective units per cubic centimeter; namely, 1 cc. of this vaccine has the same effect as 95 cc. of standard toxoid. Consequently, a single subcutaneous injection of 1 cc. suffices for protective inoculation. The serum reactions are slight. The protection appears in the third week. A simultaneous passive immunization undertaken in order to produce an immediate protection may be accomplished by the administration of 1,000 units of diphtheria antitoxin serum. The last named vaccine has already passed official inspection. The delegates were not all of one opinion with reference to the results of active diphtheria immunization.

The second major topic discussed was "Anemias and Hemorrhagic Diatheses in Childhood." M. B. Schmidt, pathologist, of Würzburg, who spoke first, differentiates two forms of destruction of the erythrocytes in anemia: the intracellular decurrent dissolution chiefly in the splenic pulp and the extracellular true hemolysis. The first type corresponds with the physiologic senile decomposition of the erythrocytes; it has its basis in the physical-chemical alterations in the stroma (colloid contraction) and is determined by the condition of the bone marrow, not by a change in the circulating blood. The second or extracellular type is accompanied by icterus, increase in the number of serum bilirubin and so on; it depends on a chemical injury to the lipid-containing surfaces and contributes to the continuance of an injury to the peripheral circulation independent of whether the erythrocytes leave the bone marrow in a normal or deficient condition. It is possible that the human blood pigment is not uniform, that there is a pathologic hemoglobin. The stroma, however, plays a leading part in the origin of anemia. Constitutional deficiencies in the bone marrow's capability of reaction are factors. Disturbance of the balance in the blood picture in ordinary so-called secondary anemias consists of increased productivity; that is, an increased new formation and an increased disintegration as a result of the rapid aging of the erythrocytes. The disorder depends also on the qualitative disturbance of erythropoiesis in the marrow, even if the damage extends to the peripheral blood, as well. There is also a decline in the number of the erythrocytes and in the amount of hemoglobin that takes place without increased disintegration, the result of the insufficient activity of the bone marrow. There are all gradations, from total disappearance of all cell systems of the marrow to pure hypochromic anemia. The cause of the last named disease in both children and adults is one of the achylously conditioned "chloranemias," deficiency in iron. Iron serves not only as material for hemoglobin but also as a stimulus to cell formation in the bone marrow and in the whole body. Only in the last named function may the iron be supplemented by copper.

M. B. Schmidt recognizes two possible forms of hypersplenic anemia: (1) that resulting from the physiologic, probably hormone, checking of the erythropoiesis of the splenic tissue and (2) that resulting from true hemolysis, the physiologic pattern for which is more uncertain. The anemia pseudoleukemia of children is etiologically not uniform; Schmidt considers the accompanying rachitis only as a stigma of the variant constitution. The unusual thing about the reaction is that erythropoiesis within and without the bone marrow runs its course like an erythroblastosis and that, on the other hand, the intramedullary and extramedullary leukopoiesis in any event assumes a hypertrophic character, which appears out of proportion to the contingent injury to the colorless cell systems. Among the clinical reports, Fanconi of Zurich discussed the primary anemias and erythroblastosis in childhood. In a number of the primary anemia cases, familial and racial factors exist; for example, in round-cell anemia (hemolytic icterus), marble bones disease, Cooley's anemia, sickle-cell anemia and congenital anemia of the pernicious variety. Primary disturbances in the bone marrow lead in greater or lesser degree to alterations in the bones, and these changes in turn lead to characteristic cranial and facial manifestations.

Rominger of Kiel spoke on secondary anemia in childhood. This disorder he designated a disturbance of the erythropoiesis through faulty nutrition, defective care of the child, intercurrent diseases and infections in particular. Essential to the development of the erythrocytes are inorganic iron, concentrates of copper, antianemic factors, hormones and vitamins. One must differentiate a hypochromic anemia and a hyperchromic anemia, a normoblastic, an erythroblastic and a leuko-erythroblastic reaction. Cow's milk anemia of nurslings is an iron anemia; goat's milk anemia depends not only on iron deficiency but, according to the nutrition of the goats, on vitamin deficiency and injury to the fat, tending toward sprue. The anemia of Heubner-Herter disease is related to severe goat's milk anemia and has been established as a kind of non-tropical sprue. Childhood pseudoleukemia seems not yet to be completely explained; certainly infections play an important part and lead to a subacute inflammation of the spleen with myeloid reaction and splenogenic hemolysis.

Finally, Catel of Leipzig discussed as the fourth paper on this topic the differential diagnosis of "hemorrhagic diatheses" in childhood. A majority of these disorders have nothing to do with "childhood diseases" but are to be etiologically interpreted quite otherwise, as scurvy, Osler's disease and so on. Catel distinguishes only six types of true hemorrhagic diatheses: familial hereditary hemophilia, sporadic hemophilia, purpura haemorrhagica, hereditary hemorrhagic thrombopathy and thrombasthenia, and finally congenital afibrinogenemia. A complete, thoroughgoing classification of the disease entities coming under the heading of hemorrhagic diathesis is as yet quite impossible. The best possible analysis of each individual case would first have to be undertaken, an analysis based on a uniform plan and exactly standardized procedures. The latter would first be worked out by a commission. A great number of individual contributions were submitted on this topic and on other aspects of pediatrics.

At the end of the congress a medical conference of the German Association for Protection of Nurslings and Infants took place. Principal topics of the papers read at this gathering were the unified administration and coordination of all infant welfare activities, breast feeding as the most vital of infant welfare problems, and care of the nursling in the lying-in hospital. Investigations carried out at Munich disclosed that, although at present almost all women attempt to suckle their infants, the period of lactation has been shortened within the last ten years. The reasons for this failure are not so much due to reluctance on the part of the mother as to defective

technic and faulty manifestation of instinct; women of a highly civilized environment should first of all be taught how to suckle. Educational courses and propaganda for mothers supplemented by the cooperative efforts of the welfare workers can do much to remedy the situation.

### JAPAN

(From Our Regular Correspondent)

Oct. 10, 1936.

#### The National Health

The Association for Encouraging Science in Japan, in response to the general expressions of dismay about the fall in the level of the national health, held its first meeting to consider methods for coping with the regrettable situation. Medical experts, from the cabinet departments, the deans of the medical departments of the imperial universities, and experts who were members of the association were present. It was decided to establish four sections of activity: eugenic, physical training, food, and clothing and shelter. The tuberculosis death rate is higher in Japan than anywhere else in the world. More than 130,000 cases of acute infectious diseases occur every year. Dysentery has shown a yearly increase. Trachoma and parasitic diseases are decreasing among students, school children and conscripts, but myopia and decaying of the teeth are increasing remarkably. Mental disease has also increased of late. The number of insane at present is 83,366, which means that there are more than twelve cases of insanity per 10,000 of population. The number of conscripts who pass the physical examination is decreasing every year, and the military authorities are afraid that half of the youth will be unable to pass the examination next year; in ten years this would bring about an alarming situation.

#### New Policy of Red Cross Society

The Japan Red Cross Society has decided on a new policy which aims to exercise a central control over the financial administration of the local branches, the administration of which heretofore has been independent of the central office. This situation caused competition between the branch offices in the different districts. It was at the same time a source of injustice, for prominent local persons, conspiring with the branch officials, often attempted to take advantage of the society for their own interest. The society will build two sanatoriums, one in Tokyo and the other in Hiroshima, for tuberculous persons who are forced to retire from military service. The former sanatorium will have 1,000 beds, the latter 1,500 beds. The new policy is estimated to require the expenditure of more than 16,000,000 yen every year.

#### Number of Medical Workers

The Home Office reports, according to the inquiry made at the end of last year, that the total number of physicians is 57,581. This is a remarkable increase, being 2,565 over the previous year and an increase of 6,789 over the year 1933. It is expected that the total will be 60,000 before long. Of these, 55,597 are practitioners, as against 49,301 in the previous year, showing an increase of 2,296. Every 10,000 of population has 7.45 practitioners, while in the previous year it had 12.45. On an average, there is one practitioner to 1,342 of population; 785 in large cities, 2,049 in towns or villages. The number of the midwives is 59,560, an increase of 1,280 over the previous year. Every 10,000 of population has 8.60 midwives. The number of nurses is 106,857. The number of dentists is 20,010, an increase of 1,102 as compared with the previous year, and out of them 18,428 are engaged in practice. Every 10,000 of population has 2.66 dentists. The number of pharmacutists is 24,957. The number of irregular practitioners is 20,204, of whom 5,970 are engaged in electrotherapy, 1,466 in ray treatment and 2,731 in heat treatment.

### A Rare Medical Diary

That the Dutch language was studied in Japan as far back as the middle of the eighteenth century is shown in the "Beginning of Dutch Study," written by Gempaku Sugita in 1815. This book has been valued as the key to the secret of the early stage of Dutch medicine introduced into this country in that century. Unfortunately the life of the author was only dimly known for lack of a biography. Recently by accident a priceless diary consisting of nine volumes, each containing about fifty pages of Japanese paper, was found in the library of the author's great-great grandchild. It contains records of daily events, chiefly concerning medicine during about twenty years in the middle of the eighteenth century. The worm-eaten pages are hard to read, and every means is now being employed to mend them. It contains such details as the price of medicine sold by the doctor to patients at that time, and the fee for a doctor's visit. It is miraculous that such a document has escaped the frequent disasters in Tokyo.

### MOSCOW

(From Our Regular Correspondent)

Oct. 26, 1936.

#### Training the Junior Medical Staff

Only recently has the question of training the junior medical staff been given much attention. To improve these bad conditions, the Council of People's Commissars issued September 8 a decision about the training of junior medical practitioners ("feldshers"), midwives, laboratory workers and others. The existing medical "technikums"—middle schools—will be reorganized in: (a) junior medical schools with a three year course, (b) midwifery schools with two years' study, (c) schools for medical nurses and nursery nurses and (d) one year courses for medical laboratory workers. In the coming year, 158,270 persons will be enrolled in all those schools.

For the four year training of stomatologists there will be two new stomatologic institutes founded at Kazan and Smolensk. Dentists will be trained in dental schools for three years. Pharmacutists of high qualification are to be trained in special pharmaceutic institutes with a four year course. Assistant pharmacutists are to be trained in special schools with a three year course, including one year of practical work. An apprenticeship for assistant pharmacutists in drug stores is permitted. This year 4,720 persons will be admitted to pharmaceutic schools and as apprentices.

#### The Moscow Cosmetic Institute

The Institute of Cosmetics and Hygiene will be opened in November in Moscow. It will provide treatment for the skin and hair, and gymnastics for the correction of obesity. The work of the institute will be under the guidance of dermatologists and physical therapists, who will also do research work.

#### Completion of Large Medical Encyclopedia

Some days ago the publication of the thirty-five volume edition of the Large Medical Encyclopedia was completed. It was accomplished under the auspices of Prof. Nicolas A. Semashko, former public commissar of health, and was begun eight years ago. More than 1,700 authors participated in the compilation of the encyclopedia, including twenty academicians, 692 professors and 1,006 scientific workers. The volumes have 6,396 articles containing 80,000 scientific terms and cover ninety-six subjects of medicine or closely allied sciences.

#### D'Herelle to Direct Institute

An all-union institute of bacteriophage is being erected in Tbilisi (former Tiflis, Georgian Soviet Republic). The founder of the bacteriophage theory, Felix d'Herelle, will be the director of this institute.

## Marriages

EDMUND MURDAUGH ELLERSON, Washington, D. C., to Miss Elsie Boyd Tucker of Richmond, Va., September 26.

HARRY HANSEN, Plainfield, N. J., to Miss Flora Gray Fraser of Englewood in Palisades Park, September 19.

EUGENE PAUL CAMPBELL, Monrovia, Calif., to DR. REBA M. LOWE of Reisterstown, Md., October 3.

EMIL UHLEIN DILLENBACK to Mrs. Fuchsia Carrick Fouser, both of Springfield, Mass., October 31.

EDWARD H. WYMAN to Miss Martha M. Mulford, both of Burlington, N. J., September 19.

NICHOLAS J. CHETT, Reading, Pa., to Miss Margaret Trotman in Elizabeth, N. J., recently.

FRANCIS EMORY BELL, Palatka, Fla., to Miss Lourline Seyden of Savannah, Ga., November 8.

CLARENCE SAMUEL BRANSON to Miss Audeen Mervin, both of St. Joseph, Mo., July 20.

ALBERT C. SANTY, New York, to Miss Rosalyn Walsh of Garfield, Ga., September 19.

## Deaths

Edwin Richard Hodge, Brooklyn; Georgetown University School of Medicine, Washington, D. C., 1892; veteran of the Spanish-American War, the Philippine Insurrection and the World War; served at the Army Medical Museum as an anatomist and later as chemist from June 1890 until Aug. 10, 1917, when he resigned to enter on active duty as an officer of the U. S. Army medical corps reserve; was commissioned a captain during the World War, during which time he was in charge of the chemical laboratory at the Army Medical School, Washington, D. C., and until Nov. 30, 1920, when he was honorably discharged from the military service; was reinstated in the position of chemist, retaining charge of the laboratory at the Army Medical School, and later at the New York General Depot, Brooklyn, until his civil service retirement June 30, 1932; formerly a member of the tenth revision committee of the U. S. Pharmacopeia; aged 76; died, September 18, in the Veterans Administration Facility, New York; of pneumonia.

Gustavus Ingomar Hogue @ Milwaukee; Northwestern University Medical School, Chicago, 1899; fellow of the American College of Surgeons; formerly associate professor of ophthalmology, Milwaukee Medical College and the Marquette University School of Medicine; veteran of the Spanish-American and World wars; attending ophthalmologist to the Milwaukee County Hospital, Milwaukee, and the Milwaukee Hospital for Mental Diseases, Wauwatosa; ophthalmologist-in-chief to the Mount Sinai Hospital; aged 64; died, September 28, of coronary occlusion.

George Metzger Todd, Toledo, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1894; president of the Association of Surgeons of the Chesapeake and Ohio Railway; formerly medical attaché of the embassy in London, England; at one time on the staff of the City Hospital, Akron, and city health commissioner of Akron; formerly visiting gynecologist to St. Vincent's, Toledo, Women's and Children's, and County hospitals; aged 65; died, September 5, of intestinal obstruction.

Carl Eugene Munger, Waterbury, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; member of the Connecticut State Medical Society and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; consulting laryngologist to the Waterbury Hospital; aged 78; died suddenly, September 26, of heart disease, while on the Cunard-White Star liner *Samaria*.

John V. Gallagher, Cleveland; Western Reserve University Medical Department, Cleveland, 1891; past president of the Cleveland Academy of Medicine; fellow of the American College of Surgeons; formerly associate professor of surgery, Cleveland College of Physicians and Surgeons; visiting surgeon to St. Alexis and St. John's hospitals; consulting surgeon to St. Ann's Maternity Hospital; aged 71; died, September 26, of pneumonia.

Royal Stuart Adams @ San Antonio, Texas; University Medical College of Kansas City, Mo., 1912; member of the Associated Anesthetists of the United States and Canada; past president and secretary of the Bexar County Medical Society; secretary-treasurer of the Bexar County Library Association; aged 46; died, September 21, of cerebral hemorrhage, chronic nephritis and arteriosclerosis.

George A. Wash, Gibson City, Ill.; University of Louisville (Ky.) Medical Department, 1894; member of the Illinois State Medical Society; for ten years a member of the city board of health and board of education; past president and secretary of the Ford County Medical Society; member of the medical staffs of St. Joseph's and Mennonite hospitals, Bloomington; aged 68; died, September 21.

Theodore Calvin Hays, Canton, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1889; at one time professor of gynecology and obstetrics at his alma mater; past president of the school board and formerly city physician; served during the World War; on the staff of the Graham and Murphy Hospital; aged 71; died, September 21, of pneumonia.

Charles Christian Walker, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Harper Hospital and the Children's Free Hospital; aged 61; died suddenly, September 28, of heart disease.

Walter D. Haynie, Kingston, Okla. (registered by Oklahoma state board of health, under the Act of 1908); member of the Oklahoma State Medical Association; president and formerly secretary of the Marshall County Medical Society; aged 60; died, September 21, in the Wilson N. Jones Hospital, Sherman, Texas.

Gaspard Lemire Marsolais, St. Eustache, Manic., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1894; Laval University Faculty of Medicine, Quebec, 1895; aged 64; died, September 14, in St. Boniface (Manic.) Hospital, of coronary thrombosis.

John Wesley Hutchison @ Saginaw, Mich.; Chicago Homeopathic Medical College, 1897; fellow of the American College of Surgeons; past president of the Saginaw County Medical Society; member of the senior staff of the Saginaw General Hospital; aged 66; died, September 13, of coronary occlusion.

George Francis Patton, New York; Baltimore Medical College, 1910; served during the World War; on the staffs of the Bronx Eye and Ear Infirmary; and the Manhattan Eye, Ear and Throat Hospital; honorary surgeon of the New York Police Department; aged 49; died, September 14, of heart disease.

William Lester Barnes @ Lexington, Mass.; Harvard University Medical School, Boston, 1904; school director; at various times town physician, health officer, and chairman of the board of health; aged 58; died, September 28, at a hospital in Boston, of cerebral thrombosis, diabetes mellitus and hypertension.

William Patrick O'Rourke, Los Angeles; Toledo Medical College, 1897; formerly medical inspector for the health department of Seattle and medical director of the city's parochial schools; at one time superintendent of the King County Hospital, Seattle; aged 70; died, September 27, in Las Vegas, Nev.

John James Mason, Vancouver, B. C., Canada; Western University Faculty of Medicine, London, Ont., 1902; past president of the Vancouver Medical Association; fellow of the American College of Surgeons; gynecologist and obstetrician to the Vancouver General Hospital; aged 55; died in September.

Darwin T. Powelson, Johnstown, Pa.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897; at one time president of the board of health of Homestead, and past president and secretary of the school board; aged 64; died, September 27, in the Conemaugh Valley Memorial Hospital.

Harry Leslie Langnecker @ San Francisco; Johns Hopkins University School of Medicine, Baltimore, 1906; associate professor of medicine (physical therapy), Stanford University School of Medicine; served during the World War; aged 58; died, September 23, in the Palo Alto (Calif.) Hospital.

Edward Reginald Secord, Brantford, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1900; past president of the Ontario Medical Association; fellow of the American College of Surgeons; surgeon to the Brantford General Hospital; aged 57; died, September 24.

**Samuel Henry McKewen**, Windsor, Vt.; College of Physicians and Surgeons, Boston, 1906; member of the Vermont State Medical Society; on the staff of the Windsor Hospital; aged 60; died, September 10, in the Claremont (N. H.) General Hospital, of acute dilatation of the heart.

**William Jefferson Mockler**, Springboro, Ohio; Ohio Medical University, Columbus, 1902; member of the Ohio State Medical Association; aged 60; formerly on the staff of the Miami Valley Hospital, Dayton, where he died, September 23, of arteriosclerosis and bronchopneumonia.

**Kenneth Kenyon Linson**, Woodhaven, N. Y.; Baltimore Medical College, 1907; during the World War served as chief medical examiner for a draft board; member of the staff of the Mary Immaculate Hospital, Jamaica; aged 56; died suddenly, September 10, of angina pectoris.

**Lenthal Azel Bollman** Ⓢ Dallas, Ore.; Willamette University Medical Department, Salem, 1906; fellow of the American College of Surgeons, member of the staffs of the Dallas (Ore.) Hospital and the Salem (Ore.) General Hospital; aged 63; died, September 29, of pneumonia.

**William Ferguson Peebles**, Clinton, Ky.; Hospital College of Medicine, Louisville, 1905; member of the Kentucky State Medical Association; served during the World War; aged 58; died, September 11, in the Illinois Central Hospital, Paducah, of carcinoma of the pancreas.

**Harold Edson Miner**, Springfield, Mass.; University of Maryland School of Medicine, Baltimore, 1905; member of the Massachusetts Medical Society; district health officer for the state department of public health; aged 54; died suddenly, September 15, of coronary thrombosis.

**Leighton Wherry Jones** Ⓢ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1897; for many years city physician; formerly on the staff of the Memorial Hospital; aged 75; died, September 18, in the Lee Hospital, of septicemia following an infection of the scalp.

**Daniel F. Jackson** Ⓢ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1902; fellow of the American College of Surgeons; served during the World War; member of the staff of the Montefiore Hospital; aged 57; died, September 6, of coronary thrombosis.

**Archibald Leonard Offield** Ⓢ Burlingame, Calif.; Cooper Medical College, San Francisco, 1905; fellow of the American College of Surgeons; formerly superintendent of the Community Hospital, San Mateo; aged 59; died, September 17, of endothelioma of the pleura.

**Thomas Albert Watterson**, Manotick, Ont., Canada; University of Toronto Faculty of Medicine, 1904; served with the Canadian forces during the World War; formerly on the staffs of St. Luke's Hospital and the Civic Hospital, Ottawa; aged 61; died, September 3.

**William Ridgway Rothe** Ⓢ Cincinnati; Temple University School of Medicine, Philadelphia, 1911; member of the Medical Society of the State of Pennsylvania; medical examiner for the Pennsylvania Railroad; aged 47; died, September 8, at his home in Newport, Ky.

**Edwin Curtis Garvin**, Cleveland; Western Reserve University Medical Department, Cleveland, 1894; member of the Ohio State Medical Association; served during the World War; aged 64; died, September 25, in St. Alexis Hospital, of pneumonia.

**Jesse Lee Prince**, Stevenson, Ala.; Medical Department of the University of Alabama, Mobile, 1899; member of the Medical Association of the State of Alabama; aged 61; died suddenly, September 29, of cerebral hemorrhage and arteriosclerosis.

**Charles C. Nail**, Moore, Okla.; Arkansas Industrial University Medical Department, Little Rock, 1889; formerly a druggist; member of the school board; aged 76; died, September 26, in a hospital at Oklahoma City, of bronchopneumonia.

**Walter Parker Irwin**, Florence, Kan.; Western Eclectic College of Medicine and Surgery, Kansas City, 1909; Kansas City Hahnemann Medical College, 1910; member of the Kansas Medical Society; aged 63; died, September 12, of heart disease.

**David F. Morton**, Perryville, Mo.; Missouri Medical College, St. Louis, 1883; past president of the Perry County Medical Society; aged 78; died, September 4, in the Barnes Hospital, St. Louis, of carcinoma of the bile ducts and myocarditis.

**Henry Adolph Owenson**, Arnegard, N. D.; Keokuk Medical College, College of Physicians and Surgeons, 1906; member of the North Dakota State Medical Association; formerly health officer; aged 51; was found dead, September 11.

**Samuel Rankin Ratliff**, Vancleave, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1901; member of the Mississippi State Medical Association; aged 63; died, September 16, of carcinoma of the stomach.

**Amedee Marien**, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, 1890; emeritus professor of clinical surgery at his alma mater; on the staff of the Hotel Dieu de St. Joseph; aged 70; died, September 1.

**James Henry Dixon**, Portsmouth, N. H.; Medical School of Maine, Portland, 1898; formerly city physician and chairman of the board of health; aged 58; died, September 20, in the Portsmouth Hospital, of cerebral hemorrhage.

**Robert Bruce Layman**, Knoxville, Tenn.; University of Louisville (Ky.) Medical Department, 1898; member of the Tennessee State Medical Association; served during the World War; aged 64; died suddenly, September 26.

**J. Ernest Dowdy**, Sandy Ridge, N. C.; University of Maryland School of Medicine, Baltimore, 1909; aged 50; died, September 19, in a hospital at Martinsville, Va., of carcinoma of the left axilla due to roentgen ray burns.

**Benjamin W. Best**, Greensboro, N. C.; College of Physicians and Surgeons, Baltimore, 1884; aged 75; formerly on the staff of the Clinic Hospital, where he died, September 24, of injuries received in an automobile accident.

**William Filmer Coy**, Vancouver, B. C., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1886; M.R.C.S., England, 1887; served with the Canadian Army during the World War; aged 73; died in September.

**John Franklin Robinson**, Manchester, N. H.; Harvard University Medical School, Boston, 1886; member of the New Hampshire Medical Society; aged 73; died, September 5, of arteriosclerosis and cerebral thrombosis.

**Arthur Charles Pariente**, New York; University and Bellevue Hospital Medical College, New York, 1932; member of the Medical Society of the State of New York; aged 27; died, September 18, of regional ileitis.

**Joseph Wilton Hope**, Hampton, Va.; Medical College of Virginia, Richmond, 1888; for many years county health officer; formerly on the staff of the Dixie Hospital; aged 70; died, September 3, of cerebral hemorrhage.

**John Ford Burnet Benton**, Valley Park, Miss.; Tulane University Medical Department, New Orleans, 1907; member of the Mississippi State Medical Association; aged 67; died, September 29, of diabetes mellitus.

**Newton I. Tibbitts**, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; on the staff of the Detroit Tuberculosis Sanitarium; aged 77; died, August 22, in Grand Rapids.

**Charles Fremont Brock**, Waltham, Mass.; University of Vermont College of Medicine, Burlington, 1884; aged 74; died, September 25, of cerebral hemorrhage, carcinoma of the urinary bladder and chronic nephritis.

**Alexander Randall Griffith**, Montreal, Que., Canada; New York Homeopathic Medical College and Hospital, 1891; medical superintendent of the Montreal Homeopathic Hospital; aged 71; died, September 2.

**George Henry Cowles**, Woodhull, Ill.; Rush Medical College, Chicago, 1896; aged 65; died, September 29, of coronary disease while driving his automobile, which went over an embankment into the lake.

**John Caldwell Foster**, Clarksville, Texas; University of Louisville (Ky.) Medical Department, 1869; Confederate veteran; aged 93; died, September 23, in a hospital at Paris, of cerebral hemorrhage.

**Elwyn Winslow Capen**, Monson, Mass.; Boston University School of Medicine, 1902; formerly member of the school committee; aged 60; died, September 19, of carcinoma of the prostate and bladder.

**Nathaniel Norris Allen** Ⓢ Houston, Texas; Kentucky School of Medicine, Louisville, 1898; member of the American Academy of Pediatrics; aged 62; died, September 22, of coronary thrombosis.

**Henry Wilkins Lewis**, Jackson, N. C.; University of the City of New York Medical Department, 1877; member of the Medical Society of the State of North Carolina; aged 80; died, October 19.

**Charles Howard Lodor**, Eustis, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1882; formerly a practitioner in Chicago; aged 77; died, October 2, in a hospital at Orlando.

Joseph Vale Cleaver, Akron, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1887; for many years on the staff of the City Hospital; aged 78; died, September 26.

Orrin P. Maxson, Weaverville, N. C.; College of Physicians and Surgeons, Chicago, 1883; formerly a practitioner in Waukegan, Ill.; aged 81; died, September 28, of duodenal ulcer and cystitis.

Henry Charles Bikle, York, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1936; aged 28; intern at the York Hospital, where he died, September 29, of pneumonia.

Samuel William Greenbaum, New York; University and Bellevue Hospital Medical College, New York, 1899; aged 61; died, September 16, of cirrhosis of the liver and bronchopneumonia.

Daniel Webster Evans @ Scranton, Pa.; College of Physicians and Surgeons of Chicago, 1894; aged 70; died, September 28, of arteriosclerotic heart disease and acute coronary thrombosis.

W. J. Hammond, Tellico Plains, Tenn. (licensed in Tennessee in 1906); aged 78; died, September 10, in the Fort Sanders Hospital, Knoxville, of carcinoma of the prostate and myocarditis.

Eugene Francois Brindjone, Butte, Mont.; Tulane University of Louisiana Medical Department, New Orleans, 1908; aged 55; died, September 27, of a self-inflicted gunshot wound.

Glenn Henry Miller @ Omaha; University of Nebraska College of Medicine, Omaha, 1919; on the staff of the Methodist Hospital; aged 45; died, September 29, of heart disease.

Edward F. Luckett @ Cheneyville, La.; Tulane University of Louisiana Medical Department, New Orleans, 1899; aged 61; died, September 29, of coronary occlusion and hypertension.

Harry Collier Mix, Oak Park, Ill.; Northwestern University Medical School, Chicago, 1909; served during the World War; aged 61; died, September 14, of cerebral hemorrhage.

Harold Eugene Rodgers @ Albuquerque, N. M.; Medical College of the State of South Carolina, Charleston, 1923; aged 40; died, September 9, in St. Joseph's Hospital, of typhoid.

James Edward Lovering, Lethbridge, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1908; chairman of the school board; aged 64; died, August 11.

Charles J. Turpin, Denver; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 67; was found dead, September 2, of a self-inflicted bullet wound.

William Parmilee Williams @ Blackshear, Ga.; Bellevue Hospital Medical College, New York, 1888; aged 69; died, September 24, in the Ware County Hospital, Waycross.

Benjamin Talbot Ferguson, Jamestown, La.; Memphis (Tenn.) Hospital Medical College, 1904; aged 57; died, September 13, in Arcadia, of a self-inflicted bullet wound.

John Moses Maness, Hamlet, N. C.; University of North Carolina School of Medicine, Chapel Hill, 1909; aged 58; died, September 24, of myocarditis and cirrhosis of the liver.

Edward Cazneau Newton, East Milton, Mass.; Bellevue Hospital Medical College, New York, 1887; aged 73; died, September 1, of bronchial asthma and myocarditis.

Frederic Remington, Rochester, N. Y.; Harvard University Medical School, Boston, 1888; died, September 12, of acute lymphatic leukemia and lobar pneumonia.

David A. Swift, Butler, Tenn.; University of Tennessee Medical Department, Nashville, 1904; aged 59; died, September 20, in Amana, N. C., of cerebral hemorrhage.

Mary Ella Mann, Nantucket, Mass.; New York Medical College and Hospital for Women, 1882; aged 77; died, September 26, of arteriosclerosis and myocarditis.

D. Harrison Billmeyer, Plains, Mont.; Jefferson Medical College of Philadelphia, 1884; aged 73; died, September 26, of peptic ulcer and hemorrhage of the stomach.

Thomas Young Carter, Westmoreland, Tenn.; University of Tennessee Medical Department, Nashville, 1905; aged 55; died, September 28, of cerebral hemorrhage.

Arturo Cairone, New York; Regia Università di Napoli, Facoltà di Medicina e Chirurgia, Italy, 1908; aged 53; died suddenly, September 19, of arteriosclerosis.

Gordon Moss Gafford, Colorado Springs, Colo.; Barnes Medical College, St. Louis, 1896; aged 73; died, September 28, of coronary occlusion and arteriosclerosis.

Benjamin F. Wilson, Golden City, Mo.; Eclectic Medical Institute, Cincinnati, 1882; aged 76; died, September 15, of cerebral hemorrhage and arteriosclerosis.

Mathew McGonigal, Loyal, Wis.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1904; aged 62; died, September 20, of arteriosclerosis.

Benjamin Franklin Gay, Hildreth, Neb.; University of Nebraska College of Medicine, Lincoln, 1886; aged 72; died, September 3, of cerebral hemorrhage.

Murdoch M. Kerr, Detroit; Detroit College of Medicine, 1899; served during the World War; aged 64; died, September 12, of carcinoma of the pancreas.

Charles Gordon Gibson @ Sioux City, Iowa; Rush Medical College, Chicago, 1900; aged 68; died, September 26, of chronic myocarditis and coronary occlusion.

Peter Livingston Carter, Buffalo; Pulte Medical College, Cincinnati, 1886; aged 79; died, September 13, of carcinoma of the stomach and secondary anemia.

Bert Suter Heintzelman @ Bayonne, N. J.; Western Pennsylvania Medical College, Pittsburgh, 1897; aged 60; died, September 24, of coronary thrombosis.

Thomas Mulligan, New Britain, Conn. (licensed in Connecticut in 1893); Civil War veteran; aged 95; died, September 21, of cardiorenal vascular disease.

Leo Robert Roth, Chicago; Illinois Medical College, Chicago, 1903; aged 56; died, September 22, in St. Anne's Hospital, of self-inflicted scalpel wounds.

Garry O. Leighner, Cincinnati; Eclectic Medical Institute, Cincinnati, 1903; aged 63; died, September 3, in the Bethesda Hospital, of coronary embolism.

Margaret Helen Bigby @ Whittier, Calif.; University of Michigan Medical School, Ann Arbor, 1917; aged 49; died, September 26, of pneumonia.

Emanuel Kauffman, Hardy, Neb.; Jefferson Medical College of Philadelphia, 1889; aged 76; died, September 2, of heart disease and arteriosclerosis.

John F. Good @ New Cumberland, Pa.; College of Physicians and Surgeons, Baltimore, 1886; aged 79; died, September 19, of cerebral hemorrhage.

William R. Callihan, Prestonsburg, Ky.; Eclectic Medical Institute, Cincinnati, 1903; aged 60; died, September 25, of a self-inflicted bullet wound.

Ludwig Lang, New York; University of the City of New York Medical Department, 1890; aged 73; died, September 4, of carcinoma of the stomach.

Albert John Kraft, Webster Groves, Mo.; Barnes Medical College, St. Louis, 1901; aged 62; died, September 24, of cerebral hemorrhage.

Amos Ogden Taylor, Altoona, Pa.; Hahnemann Medical College of Philadelphia, 1883; aged 84; died, September 27, of arteriosclerosis.

Thomas J. Herr, New York; Eclectic Medical College of the City of New York, 1882; aged 78; died, September 1, of heart disease.

Allen Ray Hickman, Manhattan Beach, Calif.; Rush Medical College, Chicago, 1894; aged 70; died, September 21, of gastric ulcer.

Peter M. Fischer, Shakopee, Minn.; Detroit College of Medicine, 1907; aged 56; died, September 29, of coronary thrombosis.

James H. Smith, Franklin, Ind. (licensed in Indiana in 1901); aged 87; was killed, September 25, in an automobile accident.

Boris Socoloff, Chicago; Loyola University School of Medicine, Chicago, 1919; aged 50; died, September 14, of heart disease.

George S. Calloway, Wallins Creek, Ky. (licensed in Kentucky in 1920); aged 68; died, September 28, of diabetes mellitus.

Harvey Preston Gillespie @ Woodfield, Ohio; Starling Medical College, Columbus, 1907; aged 68; died, September 23.

Antoine E. Cote, Falher, Alta., Canada; School of Medicine and Surgery of Montreal, Que., 1899; died, September 1.

Isaac Nathan Johnson, Martin, Tenn. (licensed in Tennessee in 1903); aged 77; died, September 2, of heart disease.

William Edgar Hover, Sarasota, Fla.; Medical School of Maine, Portland, 1888; aged 79; died, September 27.

J. Beal Powers, Macon, Ga.; Atlanta Medical College, 1884; aged 74; died, September 16, of arteriosclerosis.

## Bureau of Investigation

### THE MCGLOSSON COMPANY

#### A "Sinus Cure" Mail-Order Fraud Debarred from the United States Mails

The McGlasson Company, of Detroit, was the trade name used by Rex R. Rader, F. W. Dennis and Ellen McGlasson Dennis, his wife, in the sale through the United States mails of an alleged "complete treatment" for sinus trouble. The company also operated an agency known as the Illinois McGlasson Company, of Chicago.

No physicians, chemists or pharmacists were connected with the McGlasson enterprises. One of the advertisements used by the McGlasson Company of Detroit read:

#### "SINUS

OR CATARRH can be curbed. As a trained nurse for years I saw my remedy give lasting relief to those who had tried every known method. It comes in 2 parts with complete food chart and attacks the cause. GUARANTEED—Write Ellen McGlasson, D. 13, The MCGLOSSON CO., 305 W. Fort St., Detroit, Mich."

Circulars were sent to prospective customers in which an individual, presumably Ellen McGlasson, claimed to have been "supervisor of the nose and throat department." Just where this "nose and throat department" was located was not explained. Possibly it was located at the Chicago tailor shop where the Illinois McGlasson Company received its mail.

"Supervisor" McGlasson claimed, while observing "thousands treated for sinus," to have obtained from one of the physicians "his own special formula." With this "special formula" the McGlasson Company felt equipped to rid the world of sinus infection.

The treatment furnished persons making the required remittance consisted of a three-ounce bottle of white powder labeled "Part A," a two-ounce bottle of liquid labeled "Part B," and an atomizer for spraying the latter. "Part A" consisted of a laxative powder referred to in the advertising as the "toxic poison eliminator," and "Part B" was the secret formula of an unnamed nose and throat specialist. In addition, the company threw in some "valuable suggestions regarding diet."

According to the statement made by Mr. Rader to the Post Office authorities, the "toxic poison eliminator" consisted of Rochelle salt, 1 per cent phenolphthalein, and drops of oil of cinnamon. This "wonderful regulator" was described by the exploiter as an assistant "in mildly discharging the surplus toxins from the blood stream, which is the real cause of sinus trouble." The "special formula," according to the same report, was composed of boric acid, thymol, eucalyptol, methyl salicylate, oil of thyme, sodium salicylate, alcohol and water.

The McGlasson treatment was practically identical with the Clara Ross "sinus cure" fraud reported by the Bureau of Investigation in THE JOURNAL Dec. 15, 1934, page 1873. The Clara Ross "Toxic Poison Eliminator" consisted principally of Rochelle salt, with a small quantity of phenolphthalein and oil of cinnamon, and the ingredients of the Clara Ross "Nostril Cleanser" for sinus trouble were essentially the same as the McGlasson formula. While Rader denied to Post Office inspectors any connection with the Clara Ross enterprise, operated by one Clark Ross, husband of Miss Rader, against which concern the Postmaster General issued a fraud order on Oct. 30, 1934, evidence showed that he had been engaged since 1933 under the name "Clara Ross Remedies," operating from Windsor, Ontario, in the sale of a so-called "Clara Ross Formula" for sinus trouble, the ingredients of this "Formula" being the same as those found both in the treatment sold by the fraudulent Clara Ross Company of St. Louis and in the preparations now sold by the McGlasson concerns. Changing names and addresses is an old dodge of the mail-order "medicine man" to stay in business after the use of the mails has been denied by the postal authorities.

Sinus infection, like most chronic conditions, is subject to spontaneous disappearance for varying periods of time even without medication. Those engaged in exploiting human suffering are shrewd enough to know this, and offer treatments, remedies and cures for those conditions known to have cyclic periods of quiescence.

Although the McGlasson Company submitted to the Post Office inspectors numerous testimonials endorsing the "sinus remedy," the officers were apparently not impressed and recommended at the conclusion of the hearing that a fraud order be issued against the concerns and parties involved. A 50 per cent interest in the business is owned by Mr. Rader, 25 per cent by Mr. Dennis and 25 per cent by Ellen McGlasson Dennis. Mr. Paul N. Paulsen, who operated the Chicago agency, apparently held no stock.

The Postmaster General on Oct. 13, 1936, closed the United States mails to the concerns and parties involved.

## Correspondence

### STYLE IN MEDICAL WRITING

*To the Editor:*—The communication of Dr. Fayette E. Reed in THE JOURNAL of October 31 in criticism of style in medical writing appealed to me. I must, however, make one reservation; that is the last paragraph. I read the article with glowing approval, and then came up against the ending that "if this strikes a responsive chord in your anatomy it is a sure sign that you are over 45 years of age." I feel some resentment—as if something were put over on me; it was not quite fair to get a man to commit himself and then use it against him.

All the same I would like to support his gentle criticisms. I sympathize with him in his feeling about words which suddenly become fashionable, like "meticulous" and "evaluate," and phrases such as "per se" and "sine qua non," and then are used so much that they become almost immediately shop worn. I am now fortifying myself against the probable common appearance of the word "nisi," as a result of the way it has recently been called to the universal attention of the public, including physicians, in reports of a famous divorce case. But this use of shop worn words is a minor defect of style.

A far greater defect is the displacing of good old sound words by new words of etymological doubtfulness—if not wholly without etymological standing—because they become fashionable. Good illustrations of these are "intriguing" for interesting and "healthful" for healthy.

I can find no justification, except ignorant usage, for intriguing in the sense of interesting. From the standpoint of etymology and usage until recent years, to intrigue has had the meaning to scheme or plot, with the implication that it is none too honorable. I can remember the day when an able-bodied man would knock you down if you said he was intriguing. Now he is likely to burst a button in pride if an attractive woman calls him that. In my post-45 mind it still has a suggestion of possibilities of the penitentiary; but I would not even mind that if I could get beyond the feeling that the new usage has a suggestion of pedantic ignorance.

Another usage that disturbs my serenity in a different way is that of healthful for healthy. Apparently nobody uses healthy in print nowadays, and those who want to appear elegant avoid it in conversation, except when they are caught off their guard and talk naturally. To say healthy now is like blurting out the word legs was in this country forty years ago. As Thackeray said, they do not have legs even on pianos in America. Healthy is a good Anglo-Saxon word. Healthful, if you think about it, suggests being full of health, like full of prunes. You would think the elegant would avoid it.

I see that the word healthy is derived from that Anglo-Saxon word *Haelp*, Middle-English *Helthe*. Healthy, therefore, is a pure English word going back to Anglo-Saxon, consisting of the old root and the terminal "y," which is equally an old English form common in such words as wealthy and stealthy. Such words are strong, pure English words. There are not any better in the language.

In order to take a fall out of a word of my friends the psychiatrists that has always seemed to me to be criticizable, and at the same time to show my freedom from partisanship, I will first attack a dermatologic word in the use of which our English colleagues have especially been offenders, and that is the use of the word "dermia" as an ending. The word is derma. That's what the Greeks from whom we got it used, and the only excuse for dermia that I can see is for euphony, as Mark Twain said in explaining the derivation of equine from horse.

My psychiatric antipathy is "manic" as used in the name manic depressive insanity. If it is derived from anything it is mania, with an "a" after the "i." There is no way of getting rid of that "a" without committing mayhem. How they have elided the "a" is more than I can see. It sounds to me like an Ethiopianism, first perpetrated by some one who was not too careful in scholarship and then taken up by others for euphony again. Maybe I am wrong in this; if so and some scholarly psychiatrist will make it clear that I am, I will at least feel that this note has had some use.

The moral of all this, of course, is that the dictionary is useful if one desires to speak or write good English. As Huneker says in his "Style and Rhythm in English Prose," "A good style is direct, plain and simple. The writer's keyboard is that humble camel, the dictionary." In other words, a knowledge of the meaning of words is the first essential of a good style, and that involves the incessant use of the dictionary. And while I am at it I would like to emphasize his other dictum "A good style is direct, plain and simple." Get over the notion that you are indicating culture by cultivating a Latinized style. As Quiller-Couch says in his book "On The Art of Writing," "Don't say 'He was conveyed to his place of residence in an intoxicated condition,' say 'He was carried home drunk.'" That sort of style is easier for most of us to understand.

The whole sermon was implied in a sentence of Dr. Fishbein's recently, when he said, referring to Auenbrugger, "He wrote the most scientific sentence I believe that has ever been written: 'A chest when thumped sounds.'"

WILLIAM ALLEN PUSEY, M.D., Chicago.

#### MORTALITY FROM APPENDICITIS

To the Editor:—I was greatly pleased that in your editorial in *THE JOURNAL* June 20 you were kind enough to make reference to my mortality in the handling of the late suppurative appendicitis cases. This reference, however, is misleading in that it fails to make clear the fundamental principle for which contention was made. In season and out of season, for over thirty years, I have been insisting by both precept and example that the secret of the mortality in appendicitis lies in the application of the principle of deferred operation to the late cases of suppurative appendiceal peritonitis: not the early perforations but the cases seen for the first time on the third, fourth or fifth day of the acute spreading peritonitis. This, of course, is simply a faithful carrying out of the principles that Ochsner enunciated and insisted on.

At the annual session of the American Medical Association in Cleveland, Dr. Coller of Ann Arbor, Mich., read a paper on the same subject. I went to Cleveland to discuss the paper and the discussion will be found in *THE JOURNAL* Dec. 8, 1934, page 1759. Dr. Coller's prime contention was that after hearing my paper read before the American Surgical Association in August 1926 he had instituted the same measures at the University of Michigan, with the result that in this particular group of late suppurative peritonitis cases the mortality had been reduced from 40 per cent to about 10 per cent.

I have been contending for this principle of deferred operation in this group of cases for more than thirty years, before

the surgical section of the American Medical Association in 1909, before the American Surgical Association in 1926 and at the Cleveland session. My experience has been a continuous, consecutive, unselected one that has been maintained for a period of more than thirty years and I am convinced that such an experience has passed from the realm of speculation into the realm of scientifically demonstrated truth.

The accompanying table, which brings the matter up to date, is self explanatory.

#### Result of Operation

	No. of Cases	No. of Deaths	Mortality
1. Recurrent appendicitis .....	1,572	0	0
2. Acute appendicitis .....	989	1	0.10%
3. Acute, gangrenous, ruptured appendix, localized abscess.....	545	3	0.55%
4. Acute, gangrenous, ruptured appendix, with diffuse peritonitis: immediate operation .....	94	10	10.64%
5. Acute, gangrenous, ruptured appendix, with diffuse peritonitis: deferred operation .....	139	2	1.43%
6. Patients moribund; drainage; appendix not removed.....	12	3	25.00%
7. Appendix removed in course of other operations .....	444	0	0
Totals .....	3,795	19	00.50%

The principle for which I am contending is included in groups 4 and 5. In group 4 there were ninety-seven cases of acute, gangrenous, ruptured appendixes, with diffuse peritonitis, seen by me for the first time during the third, fourth or fifth day of the attack, with immediate operation. In this group there were ninety-four cases with ten deaths, or a mortality of 10.64 per cent. Over against group 4, in group 5 there were 139 cases of acute, gangrenous, ruptured appendixes, with diffuse peritonitis, seen by me for the first time on the third, fourth or fifth day of the attack, with deferred operation, Ochsner plan, with two deaths, or a mortality of 1.43 per cent.

LE GRAND GUERRY, M.D., Columbia, S. C.

#### WATER FILTRATION VERSUS CHLORINATION

To the Editor:—The editorial in *THE JOURNAL*, October 31, on water filtration versus chlorination fails to take cognizance of certain practical questions. The blunt assertion is made that, "if a bacteriologically safe drinking water is desired, it may be obtained by chlorination." Actually this statement might be approximately true if one were to put in a hundred or a thousand times as much chlorine as could be absorbed by the organic matter during periods of low pollution. This would be necessary, because the degree of pollution of large sources changes suddenly and enormously, as the reports of the Chicago Board of Health show. No one would drink really safe chlorinated water. In practice it is impossible to make large water supplies safe by chlorination alone.

The editorial does not consider the fact that filtration does not supplant chlorination but only supplements it. The initial chlorination can be carried on efficiently and completely, because excessive amounts can be removed before the water is filtered. Chlorination alone might be adequate protection, except against amebas and other organisms not injured by practicable quantities of chlorine, if a storage system were available. But storage tanks for holding water for an hour or two would cost almost as much as filters. Then why not have the additional protection and the superior quality of water that filtration will provide?

Of course, no mechanical device is proof against human error in its control, but at least filtration of the water supply provides an additional tool for the protection of the public health.

M. B. VISSCHER, M.D.  
A. J. CARLSON, Ph.D.  
A. C. IVY, M.D., Chicago.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### HORMONE TREATMENT FOR HERMAPHRODITISM— VIRILISM—HYPOGENITALISM—UNDESCENDED TESTIS

*To the Editor:*—I have a group of cases in which I find it difficult to decide whether some form of hormone treatment is desirable, and I come to you for advice: 1. In cases of female pseudohermaphroditism, presenting large penocclitoris, a vagina opening into the urethra, ovaries infantile and sometimes cystic, marked adrenal cortical hyperplasia, what treatment should be instituted? 2. In cases of virilism in females after puberty, when cystic ovaries are found and are surgically treated but not completely removed, what treatment should be used? 3. In hypogenitalism in males, generally associated with feminine secondary sex character, beardless face, mammary hyperplasia, penis very small, testicles generally small, prostates undeveloped, what treatment should be used? 4. In undescended testes, what is the best preparation to use in order to hasten the descent? Any assistance you may give me in these perplexing problems will be greatly appreciated.

HUGH H. YOUNG, M.D., Baltimore.

ANSWER.—1. Patients of the first type mentioned constitute one of the most pathetic groups seen by physicians. Their disorder is due to a developmental anomaly which is so fundamental as to make man's weak efforts to correct it seem quite futile. Many require expert surgical restoration, which seldom is complete and often is unsatisfactory. Medical treatment with various glandular extracts has not been promising. The suggestion is made that such cases should be admitted to institutions equipped to study the content of estrogens and androgens in blood and urine. If after a careful physical examination and such studies have been completed the patient is found to be predominantly male or female, appropriate surgical help should be given followed by a careful trial of treatment with pituitary or sex-gland hormones. It should be added that it is doubtful whether even this program would help many of these unfortunate, but it would afford the opportunity for some badly needed study.

2. Patients of the second group are more frequently seen. Some present such clear-cut syndromes as to enable the physician to make a diagnosis of (a) pituitary basophilism (Cushing's syndrome), (b) tumors or hyperplasia of the adrenal cortex, or (c) arrhenoblastoma of the ovaries. In the cases mentioned it is assumed that the last possibility has been eliminated. If in addition to the "virilism" mentioned in the question the patient has amenorrhea, purplish striae of the skin, osteoporosis of the bones, hirsutism, plethoric appearance of the face, atypical fat deposition, hypertension, elevated basal metabolic rate, glycosuria and the other symptoms described by Cushing and others, then one of the first two possibilities must be considered. If, on the other hand, the author means by "virilism" the less definite but quite distressing symptoms of hirsutism and menstrual irregularity, then we know of no diagnosis and no treatment. Such patients may represent a physiologic variant rather than a pathologic abnormality.

3. "Male hypogenitalism" as referred to is also a most indefinite condition. For many years this unfortunate group has received every available glandular product administered by mouth or by needle. At present any patient who will hold still long enough is being "shot" with something. No convincing report of success has been published. The treatment to date has been enthusiastic but ineffectual.

4. The answer to the last question regarding "the best preparation to use in order to hasten the descent of the testes" must be evasive until such time as the Council on Pharmacy and Chemistry of the American Medical Association reviews and evaluates such products. In general it may be said that the substances most frequently used are preparations of the gonadotropic principle obtained from the urine of pregnant women, the placenta or the serum of pregnant mares. Many overly enthusiastic reports of the efficacy of such treatment have appeared. At last, some conservative reports are putting in an appearance. An observer recently reported good results in 20 per cent of the cases studied. If the author of the question wishes to try such preparations he should use the products of an established pharmaceutical or biological laboratory and avoid the questionable products of unscientific commercial institutions.

It is appreciated that the answers to the questions are not definite. In defense, it may be stated that neither are the conditions inquired about definite. Treatment can never be definite for an indefinite condition. Physicians must acknowledge the inadequacy of their knowledge about such conditions and attempt to obtain this knowledge from careful study rather than from careless treatment.

### GIANT URTICARIA FROM COLD

*To the Editor:*—A woman, aged 25, for the first time last winter developed giant urticaria when exposed to cold weather. The eruption occurred several times and lasted about two hours each time. Also, there occurs a transitory swelling of the lips whenever she eats ice cream or ices. Holding a small piece of ice in her hands brought about a brief swelling of the fingers. She has never had any previous allergic manifestation. The family history reveals a suggestive asthmatic condition in her father; a sister occasionally "breaks out into hives." Will you kindly offer suggestions as to treatment? I would also appreciate any references in the literature to similar conditions. Kindly omit name.

M.D., New York.

ANSWER.—The symptoms in this case apparently come from exposure to cold, and contact with the ice caused some swelling of the fingers. These facts suggest that the urticaria is due to hypersensitivity to cold; in other words, that this is a case of physical allergy due to cold.

In 1923 Duke reported urticaria due to light and followed it up with numerous articles on allergic conditions caused by various physical factors, such as light, heat, cold and pressure. A number of other men have contributed articles on the subject. In a recent article Swineford discusses physical allergy at length and many references are given.

There would seem to be little doubt that there is such a thing as an allergic reaction caused, or at least initiated by, such physical factors as cold, heat, light and pressure. Many workers in the field, however, contend that these factors are not the prime causes of trouble but are associated with other sensitivity, such as foods, epidermals or pollens, and that the physical factors only act as contributory causes.

It would be well to read the articles of Duke and the others mentioned, in which suggestions as to the treatment are well brought out:

### IONIZATION TREATMENT IN HAY FEVER

*To the Editor:*—There is a doctor located here who believes that the ideal treatment for hay fever is "ionization." This consists of some type of nasal treatment which he accomplishes at two sittings. He believes that he produces a goodly number of cures by this method. In view of the fact that he has some following in this community, I should like to know what the treatments consist of, and your opinion.

M.D., Illinois.

ANSWER.—While nasal ionization has come to the fore during the past few years as a suitable treatment for hay fever and allergic rhinitis, its status is still unsettled. Ionization has been employed for more than a decade by certain rhinologists (Hollender, A. R., and Cottle, M. H.: Recent Advances in the Treatment of Nasal Accessory Sinus Diseases, *Eye, Ear, Nose & Throat Monthly* 5: 575, 1926) chiefly as a therapeutic aid in simple chronic rhinitis. Its use in nasal allergy is more recent, but sufficient experience has been had with the method to draw some conclusions. Earlier workers have adhered to the employment of a weak (2 per cent) zinc sulfate solution as the electrolyte. H. L. Warwick (Treatment of Hay Fever and Its Allied Conditions by Ionization, *Laryngoscope* 44: 173 [March])

1934), A. M. Alden (A Year's Work with Ionization in the Treatment of Hay Fever, *ibid.* 44:741 [Sept.] 1934) and others prefer an electrolyte of three metallic chemicals, zinc, cadmium and tin. It is doubtful whether the latter has any advantage for the electrolytic purpose.

Experiences of Warwick, Alden and several other rhinologists have been reported as favorable in the treatment of nasal allergy whether of a seasonal or a perennial character. On the other hand, the reports of a different group are encouraging for the perennial types of nasal allergy and discouraging for the seasonal condition. There seems to be little doubt concerning the value of zinc ionization as a palliative in nonseasonal allergic rhinitis, but its curative worth remains to be more thoroughly established. The reports of L. B. Bernheimer (Zinc Ionization in Nasal Allergy, *THE JOURNAL*, June 6, 1936, p. 1980), M. A. Ramirez (Disappointing Results from the Ionization Treatment of Hay Fever, *ibid.*, Jan. 25, 1936, p. 281), A. R. Hollender and Meyer Gorin (Influence of Ionization on Vasomotor Rhinitis, *Illinois M. J.* 69:493 [Dec.] 1935) and others convey this impression.

It should be added further that while from a clinical standpoint no harmful effects from nasal ionization have been observed, the possibilities of local tissue injury, at least for a brief period, must be entertained. L. W. Dean (The Fundamentals of Allergic Rhinitis, with Particular Reference to Ionization, *Ann. Otol., Rhin. & Laryng.* 45:236 [June] 1936) believes that this period is about two years.

In summarizing it can be said that:

1. Zinc ionization is a nonspecific local procedure suitable for nonseasonal types of allergic rhinitis, especially after immunization and other methods have failed to bring about a relief of symptoms.

2. It should not be heralded as a cure in spite of permanent relief of symptoms in some cases.

3. The procedure merits application only after a careful, comprehensive study of each individual case to establish a rational indication.

#### STERILIZATION AND EPILEPSY

To the Editor:—Will you kindly let me know what results, if any, have been reported in cases of epilepsy apparently associated with the menstrual or ovulation phases by sterilization or by x-ray sterilization. The case I have in mind is that of a girl, aged 20, white and single. Her epileptic seizures began apparently with the onset of menstruation, nine years ago. At onset, these seizures appeared once in two years then occurred once a year. Of late these seizures have been appearing at an average rate of once a month about the menstrual and ovulation periods. Her physical examination is negative in all respects, the only significant factor being that there is present a distinct allergic condition. As an infant she had eczema and from time to time has had attacks of urticaria. For the past nine months following a spinal puncture these attacks have become more frequent. This case has been seen in consultation with a prominent neurologist in New York City and after close observation for six months, during which treatment was given on an endocrine basis, he advises temporary sterilization by x-ray. I would like to have your opinion as to the efficacy of such treatment and also any bibliography you may have on the subject. Also, if you have one, a list of articles you may refer me to. Kindly do not publish name.

M.D., New York.

ANSWER.—The idea of an association between epileptic seizures and menstruation is an old one. The Germans have even classified what they called "ovariellen epilepsie." The only relationship that can be established, however, is the fact that there is an increased irritability at the time of menstruation. Direct relationship between the endocrine glands and epilepsy is seldom, if ever, demonstrated. F. Winter (*München. med. Wchnschr.* 70:1172 [Sept. 14] 1923) reported that he had stopped seizures for three and one-half months after x-ray exposure of the ovaries. Such results are reported, and apparently occur, after almost any treatment that influences the metabolism to any great extent. The two most recent references on the influence of endocrine organs on the genesis of epilepsy are by F. Braun (*Schweiz. Arch. f. Neurol. et de Psychiat.* 36:63, 1935) and J. J. H. M. Klessens (*Nederl. tijdschr. v. geneesk.* 80:1119 [March 14] 1936).

It is extremely doubtful that the patient in question would derive any particular benefit from x-ray treatment. If the purpose is to sterilize her, this can be done in a much better way and without destroying the organs. The patient would probably respond much better to dietetic control, such as the ketogenic diet, fluid restriction and so forth, and to phenobarbital.

There has never been any definite relationship demonstrated between epilepsy and allergy. An epileptic patient may be allergic, but there is no definite sequel.

#### IMMUNIZATION AGAINST WHOOPING COUGH

To the Editor:—A boy, aged 10 years, is well nourished and normal in all respects except for a marked sensitivity to numerous foods, plants and animal matter since babyhood. The skin tests were performed at Ann Arbor and were complete. Would immunization for whooping cough cause a reaction? At this age is such immunization necessary?

DWIGHT F. SCOTT, M.D., Sault Ste. Marie, Mich.

ANSWER.—No data are available on prophylactic whooping cough vaccination of older children. Most children of 10 have already had the disease. The best age for the injection of B. pertussis vaccine (immunizing) is the second half year of life. As the allergic child usually is predisposed to contract the more severe and protracted form of pertussis, with subsequent attacks of bronchitis and asthma as a sequel, it seems advisable to attempt immunization. Vaccine authorized by Northwestern University Medical School would not be as liable to cause severe anaphylactic or other untoward reactions as other preparations, since it contains no trace of animal protein. It is prepared from bacilli grown on human blood. The patient will probably require a total dosage of 10 or 12 cc. It may be divided into four weekly injections as follows: 1 cc. hypodermically (just under the skin); if no marked reaction occurs, 3 cc. should be given a week later; a week thereafter, from 3 to 4 cc. should be injected, and a final 3 to 4 cc. should be given a week later. A transient local erythema at the site of injection seems to be desirable; it usually disappears within a few days. Injections should not be given into the site of previous injections or into vaccination scars. The syringe and needles should be sterilized by heat; fingers should not touch the sterile plunger when vaccine is withdrawn and injected; the vial cap and the site of injection are sterilized by briskly rubbing with an alcohol sponge. Heat or wet dressings should not be applied to a local reaction, as such measures induce abscess formation.

#### NARCOLEPSY

To the Editor:—I wish to inquire about the probable etiologic factors and the type of treatment in a man, aged 26, afflicted with narcolepsy. The family history and past history are irrelevant. It seems that about four years ago he began to have attacks of flaccidity of the entire body occasionally during periods of excitement, such as getting a fish on a line and starting to draw it in. To start off with an exciting conversation, he would be unable to say anything. Seeing an exciting motion picture would cause him suddenly to become limp or have his knees crossed and for a time being unable to uncross them. These attacks last several seconds. There is no loss of consciousness. Concurrent with the onset of this phase of his illness he has periods in which he will be writing or aggregated with other people talking in which he will fall asleep. He occasionally goes to sleep while driving his car, which has caused a number of automobile accidents. He is of the obese hypopituitary type, is 5 feet 9 inches (175 cm.) tall and weighs 235 pounds (107 Kg.). Examination of the different systems gives negative results. Laboratory tests are negative, including Wassermann tests of the blood and spinal fluid. X-ray examination of the sella turcica shows diminished size, without evidence of tumor. His basal metabolic rate is -10. His eyes are normal except that he can discern light and dark only in his left eye. Please omit name.

M.D., Texas.

ANSWER.—The description given is characteristic of the narcolepsy of Gélinau, including attacks of cataplexy as well as of sleep. Little is known of the etiology in many cases, though some appear to be a sequela of epidemic encephalitis. Therapy in these cases is often unsatisfactory. Relief has been obtained through the administration of ephedrine and more recently of benzedrine sulfate. The latter is usually administered in doses of from 10 to 20 mg. on arising in the morning and if necessary an additional 10 mg. at about 11 a. m.; the drug should not be given after noon, as it is liable to interfere with sleep at night.

#### DIABETES AND CORONARY THROMBOSIS

To the Editor:—I have a patient aged 52 who has diabetes and is convalescing from an attack of coronary thrombosis. Does a high fat diabetic diet predispose such a patient to thrombosis, and should the patient be kept underweight? If so, approximately how much? Please omit name.

M.D., Ohio.

ANSWER.—The question as to whether an excess of fat in the diet leads to arteriosclerosis has been much discussed. The imbibition theory of arteriosclerosis fits the diabetic situation. This theory suggests that the fat in the form of cholesterol esters is deposited in the intima of the larger arteries, that the more fat in the blood the more readily it might be deposited. Later on calcium salts may be linked with the cholesterol in the lower layers of the intima and calcified arteries result. Aschoff, of course, has amplified this theory. Joslin believes that one of the important causes of premature development of arteriosclerosis in diabetes, apart from the influence of advanc-

ing age, is the excess of fat in the diet and in the blood, and obesity. Other men have not felt that a high fat diet predisposes to arteriosclerosis. One must recognize the work of recent years, from a prognostic point of view, in studying the level of cholesterol of the blood in diabetes.

To the question regarding the patient at hand, the patient should be reduced to about 10 per cent below normal both because of the heart and the diabetes. It is impossible to say that a high fat diet predisposes the patient to thrombosis, but such a patient should not be placed on a high fat diet.

#### INTERCOURSE DURING POSTGONORRHEAL PROSTATITIS

To the Editor:—In some instances of postgonorrheal prostatitis, pus can be expressed from the prostate by massage for months or even years after the acute stage. For how long a period must one interdict sexual intercourse in such a case? Please omit name. M.D., New York.

ANSWER.—As long as the strippings from the prostate and vesicles show pus, it is well to continue massage until they are free from pus. Whether or not sexual intercourse is permitted in this kind of a case depends entirely on the bacteriology of the fluid. If recent examinations for gonococci are negative and the smears and cultures are negative, there is no reason why the patient may not indulge. The fact that the patient has pus does not prevent sexual intercourse. When one gives permission, one must be sure that there are no organisms in the strippings.

#### BRACHIAL PLEXUS INJURY

To the Editor:—Two days ago I was called to see a patient who had injured his right shoulder twelve hours previously. Examination revealed a subglenoid dislocation of the right humerus, the right hand was moderately cyanotic and colder than the left, and the radial pulse was weaker on the right side. He complained of a numb feeling, and there was a total loss of mobility of his fingers, wrist and elbow. X-ray examination was negative for fracture. Reduction was effected without difficulty under ether anesthesia. Follow up roentgenograms were negative. A sling was substituted for the Velpau bandage to allow exercise of the fingers, wrist and elbow. After two days the only motion he has on the right side is slight flexion of his fingers and wrist. Extension, rotation and motion at the elbow are nil. Sensation of touch and of pain are present. What is the prognosis? What physical therapy should be employed? Please omit name. M.D., Wisconsin.

ANSWER.—It is difficult to advise regarding the prognosis and therapy here because injury to adjacent nerves is a possibility. The symptoms described fit in rather well with the upper arm type of brachial plexus palsy; the prognosis of this condition varies so that no general rule can be laid down, but it is generally quite good, although sometimes surgical treatment becomes necessary. Massage, passive and active exercises (when they become possible) may be recommended; also judicious use of faradic and galvanic currents, depending on which current the muscles still react to. In the meantime the possibility of brachial plexus injury should be considered. If this is thought to be present, after a reasonable length of time, if no improvement occurs, surgical intervention may be necessary.

#### NEURITIS OR MYELITIS AFTER TETANUS ANTITOXIN

To the Editor:—I am writing to you asking for information and statistics on the occurrence of toxic neuritis or myelitis following the injection of tetanus antitoxin. About two months ago a college student was given 1,500 units of Mulford's serum subcutaneously in the soft tissue of the back between the scapulae. On the second day he had a mild reaction, which quickly disappeared. This was followed on the fifth day by the usual systemic reaction of fever, chills, malaise and urticaria. The following day he noticed pain in the right deltoid associated with difficulty in raising the arm at the shoulder, and on the seventh day the shoulder was completely paralyzed. The condition is still present. The arm has been placed in an airplane splint. Just how frequent an occurrence is this? What is the prognosis? Would exercise at the time of the systemic reaction have anything to do with this occurrence? Please omit name. M.D., California.

ANSWER.—Toxic neuritis or myelitis following the injection of tetanus antitoxin is rare. Wilson and Hadden (THE JOURNAL, Jan 9, 1932, p. 123) describe three cases and refer to Lhermitte and Haguenau, who collected reports of seventy-seven such cases from the literature up to 1931. Diphtheria antitoxin, diphtheria toxin-antitoxin, scarlet fever antitoxin and antistreptococcus serums may produce similar complications. The upper roots of the brachial plexus, especially the fifth and sixth cervical, are most frequently involved. The muscles commonly affected are the serratus anterior, deltoid, trapezius, supraspinatus and infraspinatus, and these may be partially or

completely paralyzed. The neuritis is thought to be due to edema of the cord or nerve trunk and perineural tissue developing during the course of a serum reaction. The prognosis is good. Function is completely restored after a period of from three to eight months. Exercise at the time of the systemic reaction is unrelated to this complication.

#### BLUE COLORATION OF DRINKING WATER

To the Editor:—A local oil refining company has a small colony located near the plant. It has its own water supply. Well water is distributed by motor pump through copper pipes (Reverc). The water is strongly alkaline. Bacteriologically it is normal. The water turns green on standing after being drawn. If drunk first thing in the morning without draining for from three to five minutes it produces nausea almost at once with some slight abdominal discomfort and perhaps two or three watery evacuations. There are about thirty people in this colony. It would seem that all are affected to some degree with the gastro-intestinal symptoms. About six of them also manifest a mild dermatitis, the chief symptom being itching. Copper pipe was put in two years ago. Prior to that time, ordinary steel pipe was used. At that time the water never turned green and there was no gastro-intestinal difficulty. Could the copper pipe be the cause? How could this water be tested? What is the status of copper piping in the present plumbing systems? I would appreciate any suggestion that you may make. M.D., Kentucky.

ANSWER.—From the information submitted it is probable that the blue green discoloration of the water distributed through the copper pipe is due to the action of the "strongly alkaline water" on this metal. Waters with a pH of 9.5 or higher are known to be "active" with copper. The cupric product that results would depend on the dissolved salts in the well water.

This difficulty could be overcome by treating the water to reduce its hydrogen ion content to a point at which it would not be active on copper. This could be accomplished by the use of an acid or carbon dioxide. To determine the corrective measure, a chemical analysis of the water should be made.

Returning to the use of iron or steel pipe might be advisable, but there may be other good reasons for not doing so. It would be prudent to secure advice from a competent water chemist with regard to this problem, from the standpoint both of the health of the consumers and of maintenance of the water system.

#### SIALORRHEA

To the Editor:—I have a patient suffering from paralysis agitans, the most troublesome symptom being a free flow of saliva, which causes considerable dribbling and makes the patient very uncomfortable. Could you make some suggestion as to the abatement of this condition?

C. E. SAVAGE, M.D., Delphos, Ohio.

ANSWER.—The sialorrhea described is most likely due to a disturbance in tone of those structures involved in apprehension, placement and swallowing of substances, and not to increased secretion of saliva. Consequently scopolamine or stramonium may be of some value. These substances also diminish the amount of salivary secretion. If these do not produce the desired result, atropine may be used.

#### BEHAVIOR DISTURBANCE AND ENDOCRINE DISORDER

To the Editor:—Was I scientifically correct in stating that a wilful, sullen and overactive problem child, whose facial features are deformed with large teeth widely spaced, is probably the victim of a mendelian heredity, accompanied by a pituitary or glandular disturbance? Please omit name. M.D., New York.

ANSWER.—No definite answer can be given without more information about the patient. The behavior disturbance may be due to a variety of things, such as an environmental difficulty, or to one of the various forms of encephalitis which may follow infection, trauma and the like. The habit of attributing various conditions to endocrine disturbances, unless there is specific evidence of them, is to be deprecated.

#### VISSCHER-BOWMAN TEST

To the Editor:—In THE JOURNAL, October 24, you state on page 1409 in reply to a question concerning the Visscher-Bowman test for pregnancy that "the original article describing it appeared in the *Deutsche medizinische Wochenschrift* 60: 1823 (Nov.) 1934." I wish to point out that this statement is incorrect and unfair to Drs. Visscher and Bowman. The original article of these workers appeared in the *Proceedings of the Society for Experimental Biology and Medicine* 31: 460 (Jan.) 1934, in which the results with 317 cases are reported. The article you give as the original is by J. G. Menken.

M. J. SCHULOVITZ, Baltimore.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.

ARIZONA: Phoenix, Jan. 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Reciprocity*. Los Angeles, Dec. 16. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, Jan. 5. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Pfost, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: *Basic Science*. Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

KANSAS: Topeka, Dec. 8-9. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

MARYLAND: *Regular*. Baltimore, Dec. 8. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 5-6. Sec., Dr. J. Charney McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Charles Duncan, State House, Concord.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 5-8. Sec., Dr. G. M. Williamson, 4 1/2 S. 3rd St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 9. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Portland, Jan. 5-7. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, January. Sec., Board of Medical Education and Licensure, Mr. James A. Newpher, Education Bldg., Harrisburg.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

RHODE ISLAND: Providence, Jan. 7-8. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.

TENNESSEE: Memphis, Dec. 16-17. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 9-13. Sec., Dr. J. W. Preston, 28 1/2 Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, Dec. 19. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country, April 17. *Oral examinations for Group A and B applicants* will be given in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada in December. *Practical or clinical examination* will be given in St. Louis in April. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Des Moines.

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Cleveland, Jan. 9. Sec., Dr. Fremont A. Chandler, 180 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 29-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester.

### Connecticut July Examinations

Dr. Thomas P. Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held in Hartford, July 14-15, 1936. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Forty-two candidates were examined, 24 of whom passed and 18 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Yale University School of Medicine.....	(1936)		83.5*
Georgetown University School of Medicine.....	(1935)		75.3*
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1934) 79.4, (1935)		79.7
Boston University School of Medicine.....	(1934)		75
Harvard University Medical School.....	(1934) 83.5, (1935)		77.5
Tufts College Med. School (1932) 76.8, (1934) 75.5, 83, (1936) 75, 75.3			
Columbia University College of Physicians and Surgeons.....	(1935) 75, 75, (1936) 76.6, 79.7, 80.5,*		81.8*
Cornell University Medical College.....			75*
Long Island College of .....			77.6, 79.4
University of Toronto Fa .....			78.3
University of Glasgow Medical Faculty.....	(1935)		81.1
Osteopath† .....			81

School	FAILED	Year Grad.	Per Cent
George Washington University School of Medicine.....	(1935) 69.7, (1936)		70.6
Georgetown University School of Medicine (1934) 69.7, (1935)			72.7
University of Illinois College of Medicine.....	(1936)		66.3
Tufts College Medical School.....	(1934) 72.2, (1935) 68.6, 71, 71.2

† Examined in surgery.

‡ Verification of graduation in process.

§ Average grades not reported.

\*\* Permitted to appear for oral rather than written examination because of his many contributions to medicine.

### South Carolina June Report

Dr. J. Earle Boozer, secretary, State Board of Medical Examiners of South Carolina, reports the written examination held in Columbia, June 23-25, 1936. The examination covered 17 subjects and included 70 questions. An average of 75 per cent was required to pass. Thirty candidates were examined, all of whom passed. Eight physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Pennsylvania School of Medicine.....	(1935)		89
Medical College of the State of South Carolina.....	(1934)		84
(1935) 83, (1936) 78, 78, 78, 79, 79, 81, 81, 82, 82, 83, 83, 84, 84, 84, 84, 85, 85, 85, 85, 85, 86, 86, 86, 88, 89

## Book Notices

**Food, Fitness and Figure.** By Jacob Buckstein, M.D., Consulting Physician in Diseases of the Stomach and Intestines to United States Veterans' Bureau. Introduction by Harlow Brooks, Visiting Physician Bellevue Hospital. Cloth. Price, \$2. Pp. 252. New York: Emerson Books, Inc., 1936.

This volume presents in simple, nontechnical language the essential facts of nutrition in a form suited to the needs and background of the intelligent layman. From a perusal of the text one gathers that the chief objective of the author is to develop in the minds of the general public a saner attitude toward reduction, food fads, and other practical dietary problems. Such an attitude he apparently correctly believes can be developed only through an understanding of the fundamental principles of nutrition. In any case, the presentation is in accord with this plan.

Two introductory chapters trace the development of the modern diet, the art of cooking, and food preservation. Then follows a straightforward statement, running through six chapters, of the functions in the body of each of the chief dietary constituents—energy, protein, fat, carbohydrate, minerals and the several vitamins—and in another five chapters a discussion of the most important foodstuffs and beverages, including their origin and history, and their contributions and limitations in the human dietary. With the foundation laid, the remaining half of the book is devoted to the application of the knowledge thus set forth to practical dietary problems: the requirements of a normal diet and how the various foodstuffs may be used to cover them, and analysis of common dietary fads, including vegetarianism and fasting, and a discussion of the all important problem of weight control, particularly weight reduction. The last named topic receives the major emphasis. This discussion points out the dangers of short cuts to reduction through the use of products containing phenolphthalein or thyroid and the more recently employed dinitrophenol, and also shows the limitations of the many popular reduction diets such as the Hollywood eighteen day diet. It outlines the basic principles of reduction and unlike most presentations of this subject it emphasizes the foods that must be included in the diet to insure that the needs of the body for protein, minerals and vitamins are safely covered. It then works out a practical reduction plan and concludes with menus for fourteen days to provide approximately 1,500 calories, and a table of 100 calory portions to enable the reader to make other intelligent dietary adjustments.

The description thus far might apply to any one of the numerous recent elementary textbooks written for the same purpose, but it differs from the general run of such books in several important respects. It is first of all accurate in all details, both in the scientific facts presented and in their implications and in the practical dietary directions. It is moreover consistent in tone and level throughout, never for a moment going over the heads of the lay audience for whom it is intended. It is well written, well balanced and sane, one of the few books of this type that one would be willing to put into the hands of the usual layman without editing.

**Schlacke und Vitamine: Die Schlackenkost als Behandlungsweg bei Krankheitszuständen.** Von Professor Dr. Hugo Salomon. Paper. Price, 12 marks. Pp. 263, with one illustration. Leipzig & Vienna: Franz Deuticke, 1936.

This is a monograph in German on the rôle of a specific diet composed of coarse whole grain bread and an abundance of fruits and vegetables. The purpose is to provide a great deal of roughage to promote peristalsis, to eliminate constipation, and to provide an abundance of energy, vitamins and mineral elements. It is a meatless, vegetarian and fruitarian diet which, according to the author's experience, is helpful in stomach and intestinal ulcers, fevers, typhoid, tuberculosis, heart diseases, arteriosclerosis and hypertension, joint diseases, skin diseases, pancreatic disturbances, kidney disturbances, migraine and nervous conditions, and all diseases associated with constipation. The word "schlacke" means slag, or offal. Since Dr. Salomon's diet is abundant in celluloses, he names his diet "a slag diet." What he really means, apparently, is a diet abundant in roughage. A "schlacken" diet, the author holds, can be made salt free

or very poor in salt when the vegetables are cooked without salt and when all the wheat bread is made salt free. Because of its low protein content, the author claims that it is beneficial in kidney diseases and diseases associated with hypertension. The author's clinical work with this diet in the various diseases, however, is rather limited and needs further trial before definite conclusions can be made concerning its advantages in various diseases.

**Syphilis Sive Morbus Humanus: A Rationalization of Yaws So-Called for Scientists and Laymen Interested in the Damage to Man from Venereal Diseases.** By Charles S. Butler, A.B., M.D., LL.D., Rear Admiral (MC) U. S. Navy. Cloth. Price, \$3. Pp. 137, with 19 illustrations. Lancaster, Pa.: Science Printing Co., 1936.

The author sets himself firmly to a triple task: (1) to disseminate knowledge to the general populace concerning the ravages of venereal diseases; (2) to expose the fallacy of the hypothesis of the American origin of syphilis; (3) to show the unity of the so-called yaws and syphilis. In the first he has failed, in the second he is ineffectual and in the third he has succeeded admirably. The broad minded scientist and the interested physician will find much of interest in the volume, for it is only these two who will understand it. However much one may be in sympathy with the contention of the author that syphilis did not originate in the New World, his array of historical evidence in this direction is far from convincing. The description of the venereal diseases by precolumbian physicians might apply to a half dozen diseases that could be easily confused with syphilis. Furthermore, the most authoritative of the postcolumbian writers, Francisco Lopez de Villalobos and Juan de Vigo, are not even mentioned by the author. The former wrote an authoritative treatise in 1498 entitled *Las bubas*, the latter a treatise in 1517 entitled *La mal français*. Both works antedated the poem of Fracastorius by many years. The third part of the book is on a subject with which the author is familiar and which he handles admirably. He evidently has much reason for considering yaws and syphilis the same disease. This book is of much interest to the syphilologist and those interested in tropical medicine, but to the ordinary medical man it is technical and to the layman it is confusing. The partial history of the slave trade could have been shortened and the whole subject matter better arranged. Nevertheless, the book as a whole is interesting and the author is to be commended for his zeal.

**Cystoscopy and Urography.** By Jas. B. Macalpine, F.R.C.S., Honorary Surgeon and Surgeon in Charge of the Genito-Urinary Department, Sniford Royal Hospital, Manchester. Second edition. Cloth. Price, \$9. Pp. 478, with 311 illustrations. Baltimore: William Wood & Company, 1936.

This is an excellent book for the beginner in cystoscopy and for the general practitioner who does a moderate amount of cystoscopy. The cystoscopy is fully described and illustrated and the advantages of the various models are clearly presented. The author wisely states that he knows nothing of the direct cystoscope and he does not consider it. Practitioners in this country will wonder that he even bothers to consider a non-irrigating cystoscope and to trouble himself to mention the advantages of the irrigating model. Sterilization of both cystoscopes and ureteral catheters by formaldehyde vapor is described, even though this has long been known to be unreliable. The historical reviews of the various procedures are excellent. The order of examination of the urologic patient is described, but nowhere in the order of examination is excretory urography considered. The various descriptions of the normal bladder, the technic of cystoscopy and the various lesions seen in the bladder are excellently described and illustrated. The volume is considerably enlarged and revised from the first edition, but there still remain many discussions which are solely of historical interest that could be omitted without materially affecting the value of the book. The significance of hematuria is well stated and should be read by all who see urologic patients. Various other points, such as the effect of uterine displacements and tumors on the bladder, purpura, neurogenic bladder, ureteral catheterization, renal function tests, pyelovenous backflow, adrenal diseases, and abnormalities, are well discussed for a volume of this size.

Operative cystoscopy is not well described and the reviewer would hesitate to advise any one to attempt manipulation of ureteral calculi, prostatic resection, or treatment of bladder

tumors from the data presented. For example, when discussing bladder tumors the author states that "the acknowledged uncertainty of the pathological opinion has led me to rely exclusively on clinical, which actually means cystoscopic, data for my diagnosis." This is certainly bad teaching. The advantageous use of the resectoscope in the treatment of bladder tumors is not mentioned. There is nearly as much discussion of pyelovenous backflow as there is of prostatic resection. When one reads the following, one sees the inadequacy of the presentation:

The sections removed are laid out on a piece of wax in the bottom of a kidney bowl. Having removed a certain number, the surgeon looks at them with a view to deciding their aggregate size. A good way is to gather them side by side between the fingers. Estimate thus the bore of the new channel, and, allowing for inward pressure from remaining parts, consider whether an adequate passage has been provided.

There is a great deal of doubt that with the present rapid advance of transurethral procedures consideration should be given them in a volume on cystoscopy. The size of the field is such that even at present a separate volume on operative cystoscopy is necessary. The term "excretion urography" is championed by the author. This is certainly better terminology than intravenous urography, which is so widely used in this country, but certainly not as grammatically correct as excretory urography, suggested by Braasch. The discussion of this and of instrumental pyelography is quite sound. A complete index is appended.

This is an excellent volume for the teaching of diagnostic urography, but poor for operative cystoscopy.

*Les maladies des fosses nasales.* Par J. Terracol, professeur à la Faculté de médecine de Montpellier. Avec la collaboration des Professeurs J. Delmas, et al. Cloth. Price, 130 francs. Pp. 554, with 223 illustrations. Paris: Masson & Cie, 1936.

This is a comprehensive work on the diseases of the nasal fossae. It was written in collaboration with Professors Delman, Margarot and Lamarque and Messrs. Debidour, DeJean, Guibert and Tarneaud. The first part deals with the general pathology of the nasal cavities, with a consideration of the function of smell and respiration as well as of the anatomy of the circulation and such topics as epistaxis. There are also chapters describing the various sensory disturbances as well as the changes in secretion of the mucous membrane. Allergy is dealt with in one of the chapters in considerable detail. The second part of the book is devoted to the special pathology. Under this heading the structural changes such as deviation of the septum and hypertrophy of various parts are described. One chapter is devoted to the involvement of the skin at the entrance of the nose, another to acute rhinitis of epidemic character, and there are chapters on the rhinitis of infants, hypertrophic rhinitis, nasal fractures, nasal tuberculosis and syphilis, as well as chapters on atrophic rhinitis, rhinoscleroma and tumors of the nasal cavities. Nasal leprosy, foreign bodies in the nose and other topics, such as roentgenography of the nose and fossae, are given considerable attention. This is a decidedly valuable treatise presented with the usual French clarity of diction and classification. It is well illustrated, informative and an excellent addition to the literature of rhinology.

*The Microscope.* By Simon Henry Gage. Sixteenth edition, with the addition of a chapter on Micro-Inclination. Cloth. Price, \$4. Pp. 617, with 313 illustrations. Ithaca, New York: Comstock Publishing Company, Inc., 1936.

This is a storehouse of information concerning the principles of the microscope and directions for using it, the methods of preparing tissues for study and the newer and more fundamental methods in microscopy. The darkfield microscope is fully treated. This edition has a new chapter on the ultraviolet microscope, which the previous editions did not have. The ultraviolet microscope is an instrument in which small objects may be submitted to the action of ultraviolet radiation and the results observed. There must be available, therefore, some abundant source of ultraviolet such as the carbon arc or the high pressure mercury arc in a quartz tube, and certain other especially designed equipment. This entire edition has been reset and the material generally revised and rearranged. The book was first published twenty-eight years ago; happily the author has lived to revise the present edition and has been assisted by his son, whom he credits largely for the new

chapter on ultraviolet microscopy. The author especially emphasizes the study of living and fresh tissues unmodified by stains, of which in the last half century there has been developed a great profusion. The study of living and fresh tissues unstained has been partly made possible by the perfection of the darkfield, the ultraviolet, and the polarizing microscope and the microspectroscope. There is a chapter on photography and one on the history of lenses and microscopes in which there are pictures of persons who have had much to do with the development of lenses, from Jansen in the sixteenth century to Abbe, who lived on into the early part of the twentieth century. This book is encyclopedic as far as the subject of the microscope is concerned. It would be of special interest to beginning students in biology and medicine as well as to the research investigator, whose microscope has come to be such an important aid in his work.

*Les maladies nerveuses.* Par A. Van Gehuchten. Fourth edition. Revised by Dr. P. Van Gehuchten, professeur de neurologie à l'Université de Louvain. Paper. Pp. 718, with 407 illustrations. Louvain: Librairie Universitaire, 1936.

The author adheres to the purpose of his father, which was to prepare a practical textbook of nervous diseases that would be useful to medical students and general practitioners. He has purposely avoided controversial topics and rare maladies. An introductory chapter contains general information on the anatomy and physiology of the nervous system. This is followed by the main body of the work, which includes descriptions of the organic diseases of the peripheral nerves, muscles, spinal cord, brain stem, cerebellum, cerebrum and meninges. Fifty-three pages is then devoted to the functional diseases hysteria, neurasthenia and the traumatic neuroses. A satisfactory alphabetical index appears at the end. While there is a profusion of illustrations, many are small, indistinct and not well labeled. This contribution does not serve the purpose of a reference book, and the reader will often be disappointed by his failure to find information on such subjects as narcolepsy, the more modern treatment of myasthenia gravis and diseases of the sympathetic nervous system. Names of other writers are infrequently encountered, and not a single reference is given. The book fulfils the purpose which the author had in mind when he wrote it.

*Microbiology and Pathology for Nurses.* By Charles F. Carter, B.S., M.D., Director, Carter's Clinical Laboratory, Dallas, Texas. Cloth. Price, \$3. Pp. 682, with 152 illustrations. St. Louis: C. V. Mosby Company, 1936.

The major portion of the book is devoted to a well outlined and balanced course in bacteriology. The chapter on immunity is clearly presented, with an excellent discussion of the complement fixation reaction. The constant stress of relationship of the subject under discussion to practical nursing problems is noted throughout and is best observed in the chapters on disinfection and sterilization. The color plates and the other illustrations are well selected. The suggestions for laboratory exercises and questions are an aid to the instructor. References, although few, are well selected. The portion of the book devoted to pathology is rather brief and does not equal the organization and presentation of the bacteriologic section. Special pathology is included, accompanied by good illustrations. The glossary of definitions of common terms will be appreciated by the student.

*Klinik und Therapie der Herzkrankheiten und der Gefässerkrankungen: Vorträge für praktische Ärzte.* Von Privatdozent Dr. D. Scherf. Third edition. Boards. Price, 6.90 marks. Pp. 290, with 10 illustrations. Vienna: Julius Springer, 1936.

The material in this edition as in previous ones is presented in simple fashion without at the same time sacrificing much in the way of accuracy. The presentation avoids the repetitious and cumbersome style usual in textbooks. The exposition is based on the author's own experience and that of the entire Viennese school. The author not only presents the clinical facts but also attempts to explain them rationally. In this edition there is added a section on the diseases of the peripheral vessels, on the cardiac arrhythmias and on the Adams-Stokes syndrome and allied conditions. Many useful diagnostic and therapeutic suggestions will be found. Naturally, some of the observations contained are not widely held in this country, but

little controversial material is presented. For example, the idea that the pulse is small in mitral stenosis is not the universal experience. There is too much stress laid on proprietary drugs and multiple combination of drugs. However, the author rightfully condemns the current American tendency to give tremendous doses of digitalis. This excellent, simple, authoritative presentation of the modern aspects of diseases of the heart and blood vessels is highly recommended for the medical student, practitioner and internist.

**Squint Training.** By M. A. Pugh, M.R.C.S., L.R.C.P., Medical Officer in charge of the Orthoptic Department, Royal London Ophthalmic Hospital. Cloth. Price, \$2.75. Pp. 117, with 42 illustrations. New York & London: Oxford University Press, 1936.

In this booklet Miss Pugh has outlined in detail the non-surgical management of squint as it is practiced at the Royal London Ophthalmic Hospital (Moorfields). The forms of squint are classified as to physical defects, refraction error, fusion defect and psychologic, and each class is discussed as to the results to be expected by orthoptic training. Then the methods of training are gone into in detail, according to the class of squint present, and end results are recorded. Considerable space is devoted to the various types of instruments used. In this connection it is interesting to note that no mention is made of instruments that involve motion, thereby tacitly refuting the extravagant claims of the American manufacturers of recent years. On the whole, the booklet is well written and informative. As it deals with the recent exacerbation of a fairly ancient topic and presents a balanced point of view, it is worth reading.

**A Text-Book of Pathology.** By W. G. MacCallum, Professor of Pathology and Bacteriology, The Johns Hopkins University, Baltimore. Sixth edition. Cloth. Price, \$10. Pp. 1,277, with 697 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

In this edition MacCallum's textbook has been thoroughly revised, particularly with reference to the fields of endocrine disturbance, vitamin deficiencies and virus infections. The general purpose of the author remains unchanged, and the subject of pathology is approached from the aspect of etiology and pathogenesis. The morphologic and functional aspects of disease are considered in their manifestations in the body as a whole, rather than as they affect various organs individually. Such an approach is especially valuable to beginning students, as they in this way develop the habit of thinking of disease as it affects the patient as a whole. This textbook has long been a favorite with both students and teachers of pathology because of its superb illustrations and charming style. The book is intended for beginners and for that reason many subjects are treated quite briefly; references to the literature, however, chosen by the author "to direct the student to readable and comprehensive papers which review the subject and give further and more complete references," enable the student to go into the subject in more detail. This book will continue to serve its purpose of making the study of pathology a fascinating and absorbing task.

**Relief slizistoy zholudka i dvenadtsatiperstnoy kishki; gastrit, yazva, kartsinoma.** [By] I. G. Shlifer. Ukrainsky Gosudarstvenny Rentgenologicheskyy i radiologicheskyy Institut. Pod redaktsiyei G. I. Kharmandaryana. [Relief of Gastric and Duodenal Mucous Membrane in Gastritis, Ulcer and Cancer.] Cloth. Price, 9 rubles, 70 kopecks. Pp. 356, with 156 illustrations. Kharkov: Gosmedizdat Uk. S. S. R., 1935.

In his monograph, Shlifer reviews the history of the development of the roentgenologic method of study of the contour of the gastroduodenal mucous membrane. This is followed by a comprehensive discussion of the anatomy and the physiology of the gastroduodenal mucosa and the technic of roentgenologic investigation of the normal contour. Special chapters are devoted to the presentation of the value of the method in the diagnosis of gastritis, gastric duodenal ulcer, and cancer of the stomach. Well selected roentgenograms from the author's extensive material (the Ukrainian Roentgenologic-Radiologic Institute) enhance the theoretical discussion. The author stresses the point that the new method is not a supplement to the old method but a part and parcel of the roentgenologic study of stomach and duodenum. The method makes it possible to detect the early functional deviations, thus adding to the number of both direct and indirect roentgenologic signs. The literature on the subject is well covered and appended.

**The Anemias.** By Janet M. Vaughan, D.M., M.R.C.P., Assistant in Clinical Pathology, The British Post-Graduate Medical School. With notes on Normal and Pathological Erythropoiesis. By Hubert M. Turnbull, D.M., F.R.C.P., Director of the Bernhard Baron Institute of the London Hospital. Second edition. Cloth. Price, \$4.50. Pp. 309, with 33 illustrations. New York & London: Oxford University Press, 1936.

After a brief discussion of normal erythropoiesis and erythropoietic activity the author offers a rather complete classification of the anemias and thereafter condenses into a small volume a brief discussion of each of the types presented in the classification. Consideration of each of the anemias is clear, concise and unencumbered by lengthy discussions. Although reference to previously published data is largely limited to the works of English and a small group of American authors and the discussions of treatment of the various forms of anemia are somewhat too limited for practical purposes, the book should be a distinct aid to those who are familiar with the various laboratory procedures available for the study of hematologic problems in the differential diagnosis of the several anemias. Because of the extent of the subject matter considered and the author's clear cut and easily readable presentation, the book is particularly to be recommended for the recent graduate in medicine and as a reference book for the physician who has occasion only infrequently to encounter problems in anemia.

**A Manual of Practical Obstetrics.** By O'Donel Browne, M.B., B.Ch., B.A.O., Assistant Gynecologist, Sir Patrick Dun's Hospital, Dublin. Cloth. Price, \$6.50. Pp. 363, with 246 illustrations. Baltimore: William Wood & Company, 1936.

This manual is devoted entirely to practical obstetrics. The illustrations are simple, mostly line drawings, but effective in bringing out the facts to be illustrated. The text is concise and readable and brings out the essential points. The book is not entirely adapted to the American practitioner, as a terminology is employed that is not commonly used in the United States. Some of the illustrations and text describe operations in the lateral posture, which position is seldom used here. Some operations are described which are seldom if ever employed in this country, such as pubiotomy for dystocia and jejunosomy for cases of hyperemesis. The incorporation of chapters on blood typing and obstetric radiology is of definite value. The treatment of various conditions differs in many instances from that generally employed in this country; for example, the use of tents for dilation of the uterine cervix is almost obsolete, and forcible dilation of the cervix of the woman in labor by manual or instrumental methods is generally condemned.

**A Short Practice of Surgery.** By Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S., Surgeon, Royal Northern and Metropolitan Hospitals, London. Third edition. Cloth. Price, 28s. Pp. 995, with 763 illustrations. London: H. K. Lewis & Co., Ltd., 1936.

This edition, published in June, now is in one volume. The previous reviews of the first two editions placed special emphasis on the clinical applicability of the text. The authors have added thirty-two additional illustrations so as to visualize the disease processes more accurately. The various classifications help to organize the subject material and simplify its further clinical consideration. Congenital malformations, with their recognition and treatment, are quite inclusive. The chapters on bone and joint diseases are descriptive and comprehensive. This volume serves the dual purpose of furnishing an introductory textbook to the student and a readily accessible textbook to the general practitioner. The new edition is a highly satisfactory addition to the manuals of general surgery.

**Manual of Roentgenological Technique.** By L. R. Sante, M.D., Professor of Radiology, St. Louis University School of Medicine. Third edition. Cloth. Price, \$4.50. Pp. 226, with illustrations. Ann Arbor, Michigan: Edwards Brothers, Inc., 1936.

This volume was prepared primarily for aid in the training and supervision of roentgenographic technicians and secondarily for the use of the general medical profession. It is written in simple language and published by the lithographic printing method to provide flexibility in making additions to and eliminations from the text. After a brief historical introduction the book develops the subject from a physical and mechanical point of view of x-ray technic and then discusses essential factors in roentgenologic procedure and dark room technic. The remain-

ing portions of the book are concerned with standard precautions for protection from excessive x-ray exposure and instructions to the technician. The book is plentifully supplied with excellent illustrations, with pages for inserted notes and with a comprehensive and excellent index. Its wide use in schools for x-ray technicians has established its practical character.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Voluntary Patient at Government Narcotic Farm Entitled to Release on Demand.**—The federal narcotic farm at Lexington, Ky., was constructed by the federal government primarily for the confinement and treatment of prisoners convicted of offenses against the United States who are addicted to the use of narcotic drugs. Provision is made, however, whereby any narcotic addict may voluntarily become an inmate of the institution, subject to the following conditions:

"No such addict shall be admitted unless he voluntarily submits to treatment for the maximum amount of time estimated by the Surgeon General of the Bureau of the Public Health Service as necessary to effect a cure. . . . Provided, That if any addict voluntarily submits himself to treatment he may be confined in a United States narcotic farm for a period not exceeding the maximum amount of time estimated by the Surgeon General of the Bureau of the Public Health Service as necessary to effect a cure of the addiction or until he ceases to be an addict within the meaning of this chapter: And provided further, That any person who voluntarily submits himself for treatment at a United States narcotic farm shall not forfeit or abridge thereby any of his rights as a citizen of the United States; nor shall such submission be used against him in any proceeding in any court, and that the record of his voluntary commitment shall be confidential and not divulged."—*Title 21, United States Code, Annotated, sec. 232.*

Lloyd, a narcotic addict, applied for admission as a voluntary inmate to the narcotic farm, agreeing to the conditions of admission, and was admitted. Before the maximum amount of time estimated by the Surgeon General of the Bureau of the Public Health Service as necessary to effect a cure had expired, Lloyd demanded his release. The demand was denied and he petitioned the United States district court, eastern district, Kentucky, for a writ of habeas corpus.

The superintendent of the narcotic farm, in answer to the petition, asserted that Lloyd was still an addict with extremely unstable personality, with inebriate impulses and emotional instability, that he had not received the maximum benefit of the prescribed treatment, and that in the opinion of the medical board he should not be released from the institution. The superintendent further contended that Lloyd had signed an agreement to comply with all the conditions of admission and thereby granted to the officials lawfully in charge of the farm authority to use any reasonable method of restraint to prevent his departure until eligible for release under the terms and conditions of his contract. The contention of the superintendent, said the court, was apparently that the purpose of the act was to authorize specific enforcement of the terms and conditions of the contract entered into by a voluntary inmate by subjecting him to compulsory confinement at the institution for the time specified in the contract. But, said the court, if the act be so construed, serious constitutional barriers to its validity would be encountered. The fifth amendment of the federal constitution provides that no person shall be deprived of liberty without due process of law and the thirteenth amendment provides that involuntary servitude, except as a punishment for crime whereof the party has been duly convicted, shall not exist within the United States. The contention urged by the superintendent, the court observed, would necessarily carry with it the implication of power to enforce on a voluntary inmate all prescribed rules and regulations, including the power to coerce labor in shops, factories or other industries established on the farm for the manufacture of commodities and supplies for the United States government. The fact that Lloyd at some previous time consented to submit himself to confinement does not withdraw the enforced imprisonment from the condemnation of the provisions of the federal constitution

referred to above. The intent of the constitutional provisions could be defeated with obvious facility if citizens could be held to involuntary servitude or enforced imprisonment, through the guise of contracts.

Furthermore, the court said, the fact that an act of Congress authorizes the making of a certain character of contract does not carry the implication that Congress intended to grant to one contracting party the power or authority to use force or coercion on the other party to prevent his breach of the contract. The guaranteed constitutional rights embrace the right not only to make contracts but also to terminate or renounce them, leaving the remedy for the breach of civil damages, subject only to the jurisdiction of equity to decree specific performance in proper cases. The fact that the beneficial effect of the act as a regulatory measure, designed to promote law observance, good order, morals, peace and safety, may be defeated without the power to enforce observance of admission agreements in cases of voluntary patients is immaterial, the court said. The right to regulate such matters within the several states is not delegated to the federal government but is reserved to the states. The federal laws that have been enacted to regulate, within the several states, the possession of and traffic in narcotic drugs have been upheld because they are revenue measures. Their constitutional support rests solely in the taxing power granted by the constitution to the federal government. Such results as may be derived from them within the several states in the promotion of peace, morals and general good order are merely incidental and afford no basis for their constitutional validity.

Compulsory detention of a voluntary patient in the institution, the court continued, as a means to accomplish his enforced observance of the terms and conditions of his contract of admission, is entirely out of harmony with the letter as well as the manifest spirit of the law. The act is charitable and benevolent in respect to voluntary patients and not penal or criminal in its nature. The government may fix the terms and conditions on which admission to the narcotic farm and the privilege of sojourning there may be granted to those who voluntarily seek to avail themselves of its benefits and opportunities for treatment. With respect to such patients, however, compliance with such terms and observance of all prescribed rules and regulations may be enforced only so long as they voluntarily remain as patients or inmates of the institution. The privilege of abiding at the institution may be denied or withdrawn, but the law does not authorize coercion of continued acceptance of the government's charity and benevolence by subjecting voluntary patients to compulsory confinement or detention at the institution, even though such enforced confinement may be for their personal welfare and in specific performance of the patient's agreement to submit thereto.

The court accordingly granted the petition for a writ of habeas corpus.—*Ex Parte Lloyd, 13 F. Supp. 1005.*

- Middle Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Alfred Lewy, 25 East Washington St., Chicago, Chairman.
- Mid-Western Section, American Laryngological, Rhinological and Otolological Society, Chicago, Jan. 11. Dr. Frederick A. Figi, 436 Tenth Ave., S.W., Rochester, Minn., Chairman.
- Puerto Rico, Medical Association of, San Juan, Dec. 18-20. Dr. Dolores M. Pinero, Ave. Fernandez Juncos, Parada, 19, Santurce, Secretary.
- Society of American Bacteriologists, Indianapolis, Dec. 28-30. Dr. I. L. Baldwin, College of Agriculture, University of Wisconsin, Madison, Wis., Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Memphis, Tenn., Jan. 13. Dr. Charles D. Blassingame, Physicians and Surgeons Bldg., Memphis, Tenn., Chairman.
- Southern Surgical Association, Edgewater Park, Miss., Dec. 15-17. Dr. E. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Section, American Laryngological, Rhinological and Otolological Society, San Diego, Calif., Jan. 30-31. Dr. David R. Higbee, 3245 Fourth Ave., San Diego, Calif., Chairman.
- Western Surgical Association, Kansas City, Mo., Dec. 11-12. Dr. A. H. Montgomery, 122 S. Michigan Blvd., Chicago, Secretary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

Epidemic Lymphocytic Meningo-Encephalitis: Report of Thirty-Seven Cases Occurring in Philadelphia. E. L. Noone, K. Habel and Helen E. Riggs, Philadelphia.—p. 870.

**Congenital Muscular Hypertrophy.**—In addition to the case of Hall and his associates, possibly five other cases have been reported in the literature. In their case there were an abnormally high excretion of creatine and creatinine in the urine and an exaggerated response in the creatine excretion to variations in the amount of protein ingested. The concentrations of potassium, inorganic phosphate and phosphatase in the blood serum were high. The greatly hypertrophied voluntary muscles were normal histologically and in their reaction to electrical stimulation. Any of the main features of the syndrome may be subject to considerable variation. The pathologic process responsible for the disturbance in the extrapyramidal system is uncertain. The four patients whose cases were reported previously died during the first twenty months of life. Two of DeLange's patients apparently died as a result of the disease. The authors' patient has lived longer than any of the others. After his discharge from the hospital he was admitted to an institution for the feeble-minded, and he was reported in January 1936 to be thriving, at the age of  $2\frac{1}{2}$  years, without any change in his muscular overdevelopment. The differentiation of the syndrome from myotonia congenita (Thomsen's disease) may be made on the basis of the age at which it appears, the clinical picture, electrical stimulation of the voluntary musculature and biopsy of muscles. In congenital muscular hypertrophy, hypertonia associated with massive hypertrophy of the musculature of the body is present at birth, there is no difficulty in the initiation or cessation of movements, the reactions to electrical stimulation are normal and biopsies show normal muscles. The syndrome appears to be easily differentiated from the pseudo-hypertrophic type of muscular dystrophy. The latter condition is invariably accompanied by muscular weakness and exhibits histologic degenerative changes in the muscle fibers. The high total creatinine nitrogen coefficient observed in the present case is of unusual interest. Schiff and Balint, while studying the excretion of creatine and creatinine in the urine of infants with various diseases of the muscular system, observed one patient with a high total creatinine coefficient. Their diagnosis was encephalitis, but their observations suggest that their case might belong in the group under discussion. The increase in the concentration of potassium and inorganic phosphate in the serum, as well as the increase in the excretion of creatine and creatinine in the urine, may be related to the increase in muscular development and metabolism, since the concentrations of potassium and inorganic phosphate are normally higher in muscle tissue than in blood serum. The authors cannot explain

the occurrence of a high phosphatase content in the serum of their patient. There was no evidence of disease of the bones or of the liver in the clinical observations or roentgenograms.

**Second Attacks of Poliomyelitis in Macacus Rhesus Monkeys.**—Toomey states that Macacus rhesus monkeys that received injections of virus either by way of the gastro-intestinal tract or intracerebrally and that had paresis or limited palsies as a result contracted the disease again when subsequently given injections of homologous virus intracerebrally. Animals that had severe quadriplegia after the introduction of the first or of any subsequent injection of the virus seemed to be protected from the effects of doses ordinarily used in experimental work. The animals that showed ordinary quadriplegia and recovered, irrespective of the dose of the virus, were probably immune, since they did not contract the disease again even when repeated intracerebral injections were given of doses as high as 2 cc. of a 10 per cent virus suspension. Quadriplegia developed between six and ten days after injection in five animals that were given 0.2 cc. of a 1 per cent solution and also in five others given 2 cc. of a 10 per cent solution of the same virus suspension. Irrespective of the original dose, the animal that had quadriplegia seemed to be protected not only from the usual dose required to produce the disease but from many multiples of that dose. Paul and Trask's lack of success with reinoculation may be due to the fact that they employed the same dose and percentage of virus for both the original and the subsequent injections. When they used a heterologous strain of virus, they were able to reinfect the animals easily, as were Burnet and MacNamara. It may be that virus differs only quantitatively and not qualitatively. The evidence that there are qualitative differences is based on the generally accepted belief that an animal is not reinfect with a homologous strain of virus but that it may be reinfect with a heterologous strain. This report casts doubt on the validity of the assumption that reinoculation of homologous virus cannot reinfect monkeys.

**Radiation Therapy of Abdominal Malignant Growths.**—Merritt avers that the diagnosis of a gastric malignant condition can be made with a higher degree of accuracy by the roentgen examination than by any and all other methods, not excepting exploration and the microscopic section. The sensitivity of the malignant stomach to irradiation is readily determined by subjecting the patient to radiation therapy. Now that the fractional method of Coutard or its modification is coming into general use, one may determine within a period of two or three weeks at most the degree of tumor sensitivity,

which applies to malignant neoplasms of the stomach as well as to other suspected intra-abdominal malignant tumors. The author has advocated preoperative irradiation of obscure abdominal tumors for some years and has never observed that it delayed or prevented recovery. On the other hand, there is indubitable proof of its great value as a life saving measure. Of thirteen patients treated since January 1934, three are living and apparently well and free from all evidence of disease, roentgen examinations of their stomachs having been made recently. One is living with roentgen evidence of disease. Nine are dead of the disease. These cases were treated without regard to the condition of the patient or the extent of involvement of the stomach, and most of those who died and one of the living patients were in a dying condition when treated. Subjects suffering from malignant disease of the stomach tolerate treatments very well. Treatments are given daily, after the modified Coutard technic.

**Long Target-Skin Distances in Roentgen Therapy.**—Quimby shows that relative depth doses for various target-skin distances can be calculated according to the inverse square law. If actual depth doses are known for any distance, they can be calculated for any other, at least between 50 and 150 cm. The increase in depth dose with distance is small near the surface and becomes steadily greater with increasing depth. It is not, however, advantageous to use distances greater than ten to twelve times the depth of the tumor. It is known that the time necessary to deliver a specified amount of radiation increases as the square of the distance. From a practical point of view, this increase in time is an important economic factor. From a biologic aspect it introduces complications because of differences in tissue recuperation. It would be expected to make the use of long distances more valuable in radioresistant than in radiosensitive conditions. The problem of localization of the field with regard to the lesion becomes increasingly important with the use of longer distances.

**Supervoltage Roentgen Rays in Cancer Therapy.**—From clinical observations, Ward and his associates are convinced that 800 kilovolt roentgen rays have a distinct advantage in depth dose over 200 kilovolt roentgen rays, and that this advantage becomes more apparent when smaller ports are used. Excellent primary regression has been obtained in a few cases in almost every type of neoplastic disease in which the 200 kilovolt units might be effective. Among these there have been ten cases of carcinoma of the urinary bladder and seven cases of carcinoma of the cervix uteri that serve as a yardstick with which to measure progress. Of the ten cases of advanced carcinoma of the urinary bladder treated by supervoltage roentgen rays, four show complete primary regression of the disease, which has now lasted from eight to fourteen months without recurrence. One patient probably had complete primary regression of the disease, but 12 millicuries of radon in gold seeds was added cystoscopically five weeks after completion of the roentgen therapy. Nine months has elapsed without recurrence. In one patient the major portion of the bladder tumor regressed, but 29 millicuries of radon in gold seeds was inserted through a suprapubic cystostomy in the extravescical extension and mucosa over it five weeks after completion of the roentgen therapy, and in eight months there has been no evidence of recurrence. There were four cases in which neither primary nor late complete regression of disease was obtained. One of these patients is living fifteen months after treatment, but the others died eleven, three and three and a half months after completion of roentgen treatments. These cases were treated with only two skin ports, a center anterior and posterior 12 cm. circular skin port; the smallest dose given was 3,000 roentgens to the anterior and 3,000 roentgens to the posterior field, while the larger doses were 4,200 roentgens to each of two opposing fields. By this type of set-up all the treatment given was the most effective treatment that could be given to the bladder itself without irradiating the whole pelvis. Of the seven cases of advanced carcinoma of the cervix uteri treated by supervoltage roentgen rays, two of the three cases of carcinoma of the cervical stump have shown complete primary regression of the disease for ten and six months and the other one has been apparently free from disease for ten months, but roentgen therapy was supplemented by 750 millicurie hours of radium at 1 cm. distance to the left side of the

vaginal vault and remains doubtful. Two of the four regular cervix cases have shown complete primary regression of disease, which has persisted for ten months. The other two patients did not show complete primary regression and died four and nine months after completion of treatment. These seven patients received a minimum of 3,000 roentgens to each of two ports, and a maximum to six pelvic ports made up of 1,400 roentgens to each of four lateral pelvic ports and 2,450 roentgens to each of two opposing central ports.

**Use of BCG Vaccine.**—Kereszturi and Park feel that BCG vaccination is free from danger to children. They have had the same experience with 515 exposed BCG children. On the average, in some respects they did as well as the corresponding controls and in other respects better. Four of them died of tuberculosis. All four were examined post mortem and studied bacteriologically, and tubercle bacilli of human type, characteristic by culture and animal inoculation, were recovered from the organs in three cases, which means that human tubercle bacilli and not the BCG caused their death. The pus of thirty-one BCG abscesses was aspirated, cultures were taken, and the bacilli were obtained in twenty-seven. The stay of the bacilli in the human body varied from one to ten months. An increase in virulence could not be determined. In their investigation whether the BCG culture is effective in preventing tuberculosis among vaccinated children the authors observed 269 orally vaccinated BCG children, 421 parenterally vaccinated BCG, 345 controls known since birth and 410 controls not known from birth with negative initial Mantoux tests. The tuberculosis death rate among the controls known from birth is more than twice as high as among the orally vaccinated babies. On the other hand, the negative Mantoux control cases showed a tuberculosis death rate about four times as high as that among the corresponding treated group; that is, among the parenterally vaccinated BCG babies. The diagnosis of the cause of death can be considered accurate, as all but five of 101 children who died of tuberculous and nontuberculous diseases died in hospitals. It is worth while to make every effort to diminish the risk of death due to tuberculosis among children of tuberculous families by giving the BCG vaccine as early as possible. Through the use of BCG vaccine parenterally the death rate was cut only to its fourth. However, if a way could be found to reach all children of tuberculous families at birth and a means obtained to separate them from tuberculous contact, as Wallgren did, three months before and as long after vaccination until allergy to tuberculin appears, the BCG vaccine could be made much more effective. Therefore its use should be urged as a public health measure for the prevention of tuberculosis in those who have not yet become infected and who may later be exposed to tuberculosis in their own families.

**Sedimentation Rate in Estimating Activity in Tuberculosis.**—Kelley performed 1,381 sedimentation rates on 290 patients with pulmonary tuberculosis. A close correlation was found between the sedimentation rate and the roentgenogram in a study of the activity of the tuberculous process. In a series of 106 cases the leukocyte count did not appear to be quite as accurate an index as the sedimentation rate in determining activity. The comparison between the sedimentation

rate and the other clinical and laboratory observations, such as sputum, presence of moderately coarse râles and symptomatic activity, was definite but not as marked as that between the sedimentation rate and the x-ray changes. The sedimentation rate quite accurately followed the course of the disease and in some cases gave warning of relapses before new shadows appeared in roentgenograms. In 80.5 per cent of the cases with pleurisy, the sedimentation rate was abnormal. Simplification of the technic by making only one reading at the end of an hour would prove quite practical for clinical work.

**Modified Dorsal Sympathectomy for Raynaud's Disease of Upper Extremity.**—Smithwick has employed a modified dorsal sympathectomy in twenty-three cases of vascular spasm of the upper extremities. The technic consists of a vertical paramedian incision about 6 cm. long, 3 cm. from the midline, the incision being centered opposite the second dorsal spinous process. The inner inch of the third rib and corresponding transverse process are resected. The inner  $1\frac{1}{2}$  inches of the second and third intercostal nerves are resected from the intervertebral foramen outward. The dorsal sympathetic trunk is identified between the second and third dorsal ganglions and is sectioned just below the third dorsal ganglion; the upper end of the sectioned trunk is brought out of the thorax and sutured without tension to the muscles of the back. The intercostal nerves are resected in order to guarantee a complete ramisection and also as an additional safeguard against regeneration. This results in a zone of anesthesia about the thorax, which becomes so narrow in a few months that it is a matter of no importance. The axillary region remains quite anesthetic and perspiration is inhibited. By this operation all possible sympathetic connections between the dorsal cord and the brachial plexus are severed except those which might be contained in the first dorsal nerve. The author believes that only preganglionic fibers are divided in this operation and that the postganglionic fibers to the arm are left intact. The clinical results to date would indicate that few if any efferent sympathetic fibers to the hand pass over the first dorsal nerve. From a clinical point of view this modified type of sympathectomy is not followed by recurrence of vascular spasm due to the action of epinephrine on the blood vessels in the sympathectomized area. This was the greatest drawback to the operation of cervicodorsal ganglionectomy and rendered that operation unsatisfactory.

**Peritonitis and Gastro-Intestinal Surgery.**—Shambaugh declares that there are certain considerations which question operative soiling as the important cause of fatal peritonitis.

The natural defensive powers of the peritoneum in experimental animals are sufficiently great to withstand a definite and considerable inoculation with bacteria, except those of great virulence, provided this inoculation is not a prolonged feeding in of organisms as from a suppurative focus or from an opening into the lumen of the intestine. That the peritoneum in man is probably almost equally resistant is evidenced by the frequent prompt recovery from peritonitis after the surgical removal of a gangrenous appendix. In addition, there is the clinical observation that there is frequently more or less unavoidable soiling when the intestine is opened at operation, and yet fatal peritonitis is the exception in such cases rather than the rule. In order to determine the relative importance of peritonitis as a cause of death following operative procedures on various parts of the gastro-intestinal tract and to investigate the cause of the peritonitis in these fatal cases, the deaths following gastro-intestinal surgery at the Peter Bent Brigham Hospital from 1913 to the present time were analyzed, only those being included in this study which were submitted to postmortem examination. Of ninety-one cases studied, there were twenty-three deaths of peritonitis. Necropsy was done in twenty-five fatalities and in these the operative procedure had been gastric resection in thirteen cases, gastrojejunostomy in nine cases, gastrojejunostomy with pyloroplasty in three cases and gastrostomy in one case. In eight cases the operation had been undertaken for peptic ulcer and in the remaining seventeen for carcinoma of the stomach. In these twenty-five cases, peritonitis was the cause of death in four. Of fourteen surgical cases of the small intestine in which necropsy was done, two deaths were due to peritonitis. Of fifty-two fatalities in which surgery of the large intestine was performed, peritonitis was found at necropsy to be the cause of death in seventeen cases. A study of the postmortem observations in the twenty-three cases of fatal peritonitis reveals the significant fact that in all but six cases a definite focus of contamination was found. This focus proved to be a grossly leaking anastomosis in five cases, a perforation through a carcinoma in three cases, and a fecal leak in three other cases, due respectively to an open appendiceal stump, the slough caused by a tight suture and the tearing out of a cecostomy tube. In five cases the infective focus was gangrenous intestine caused by impaired blood supply, and in one case the focus was a fulminating wound infection involving all layers of the abdominal wall. In only six instances, therefore, could the fatal peritonitis be attributed to contamination of the peritoneal surfaces at operation.

**Benign Metastasizing Hemangioma.**—Robinson and Castleman find that only four apparently authentic cases of hemangiomas have been reported: by Borrmann, Shennan, Ewing and Geschickter and Keasbey. They have given rise to considerable discussion because the existence of such a group has an intimate bearing on the question of the essential similarity of benign and malignant processes and because they are difficult to classify. The authors have recently had the opportunity to study a case which helps to clarify the paradox of a metastasizing benign tumor. It seems to them that the case they report is a connecting link between the four cases cited in the literature and the true angiosarcomas. There is evidently an example of an apparently histologically benign tumor giving rise to malignant metastases. To assume that this is a case of multiple tumors, one would have to admit that there were numerous hemangiomatous rests, such as Ribbert (quoted by Borrmann) describes, which began to grow under the influence of local or general factors. If this were true, one would expect these secondary tumors to have been discernible either at the same time as the original tumor or certainly within a shorter period than one year. Since it is highly improbable that this is a case of multiple tumors but rather that the lesions that appeared following the original breast tumor were really metastases, they must conclude that they are dealing with a process which was malignant from the onset and that the primary tumor, in spite of the absence of histologically malignant properties, was not benign. They feel that, because the histologic structure of their case is similar to the quoted cases, especially those of Borrmann and Ewing, it is probable that the latter were also primary malignant tumors. This is in agreement with Shennan's concept that it is the occurrence of metas-

tasis which should be the deciding factor and not the histologic features. The response of this tumor to various forms of radiation shows it to be highly radioresistant.

**Irradiation of Ovaries as Supplement to Surgical Therapy for Mammary Cancer.**—Witherspoon believes that clinical and laboratory evidence and general observations support the hypothesis that roentgen irradiation of the ovaries, with subsequent estrogenic inactivity, is beneficial as an auxiliary treatment to surgical intervention and radium therapy in the treatment of carcinoma of the breast. The theory that general systemic influences, such as hormone stimulation, are a causative factor is becoming important. The extremely malignant character of cancer of the breast as a complication of pregnancy is widely recognized, and evidence is accumulating, based on general clinical impressions, which suggests that carcinoma of the breast is many times more malignant and less curable in young women in whom the estrogenic principle is still active than in patients who have passed the menopause. As previously stated, the growth-promoting action of estrogenic substance is the main factor in mammary development at puberty. Watson reported marked development of the breasts in a girl 19 years of age with hypogonadism and amenorrhea, who was given estrogenic substance in large doses. Geschickter, Lewis and Hartman investigated its action on hypertrophy of the breast and the formation of a tumor. They concluded that gynecomastia in the male and virginal hypertrophy and fibroadenoma in the female breast are dependent on pathologic variations in the action of estrogenic substance on the duct epithelium and surrounding breast tissues. These observers have demonstrated the presence of the estrogenic principle in a fibroadenoma of the breast. Since the rate of growth of mammary cancer in animals is accelerated by the estrogenic principle, and since hypertrophy of the breast and the formation of a benign tumor in human beings are also influenced by it, it seems logical to conclude that a malignant growth of the human breast may likewise be affected by the action of estrogenic substance. Bilateral oophorectomy retards the rate of growth of a malignant tumor of the human breast and causes regression of metastatic nodules. In the treatment of mammary carcinoma, therefore, all estrogenic activity should be destroyed by roentgen irradiation of the ovaries, since the presence of the hormone is an exciting growth factor on the breast and on the mammary cancer. Induction of the menopause, especially in young women, in the treatment of carcinoma of the breast may seem somewhat radical, but in view of the tremendous growth-promoting properties of the estrogenic principle on secondary sexual tissue this treatment is rational. Only clinical application of this auxiliary therapy will prove its value.

**Fat Embolism.**—Jirka and Scuderi used eleven dogs, weighing close to 12.5 Kg., in their experiments. Sterile oleic acid was given intravenously to six animals and sterile olive oil to five. Doses of varying amounts were used in each experiment.

They found that 0.16 cc. of oleic acid or of olive oil per kilogram of body weight is sufficient to produce changes in the pulmonary fields that may be visualized roentgenographically. These changes can be demonstrated for from five to seven days after the injection and as shortly as twenty minutes after the oil has been placed in the blood stream. A diffuse haziness or cloudiness of the pulmonary fields has been persistently present in all the experimental animals. The uniformity of their results convinces the authors that droplets of fat in the pulmonary circulation, if present in sufficient number, will always produce changes in the pulmonary fields that are detectable in roentgenograms. Roentgenograms of patients suffering from clinical fat embolism should be of definite diagnostic aid.

**Primary Streptococcal Peritonitis.**—Analysis of forty-two cases of streptococcal peritonitis leads Pollock to believe that the condition can be readily recognized in most instances when it is recognized that it is seen most frequently in infants, that it is usually preceded by pharyngitis, that the abdominal symptoms, early distention and constant pain and tenderness, are generalized and start from two to three days after the subsidence of the infection of the respiratory tract, and that the condition is definitely diagnosed by abdominal puncture, the gram-positive streptococci with pus cells being pathognomonic. The treatment depends on the severity and stage of the illness, each case being a rule unto itself. The mortality, at its lowest, is 80 per cent. The frequent severe sepsis interdicts early operation, while the peritonitis is generalized. In the interim, a continuous intravenous drip of saline solution, repeated transfusion of blood and the injection of pooled antistreptococcus serum is indicated. Laparotomy is valueless and even dangerous when the sepsis is severe. However, when the general infection is not marked and there is evidence of much peritoneal fluid, improvement is often observed when drainage is obtained by the simplest and most rapid means. The large walled-off abscesses should be drained.

- \*The Head-Low Position in Tonsillectomy. C. E. Earnest and H. S. Rusk, Pueblo.—p. 692.

**Head-Low Position in Tonsillectomy.**—Earnest and Rusk assert that the view obtained in the "head-low" position enhances complete removal of all tonsillar tissue, the least trauma to the tissues, the avoidance of bleeding and the prevention of complications. The result is a confident surgeon, not hurried or worried by the difficulties of the operation. The most satisfactory support of the head is one that remains parallel to the table in tilting, in which position the head and muscles are at rest, and there is no laryngeal obstruction if the support is so that the neck is straight and in line with the axis of the body. Both the anesthetist and the surgeon are seated at the head of the patient on rather low stools, the latter a little lower. The patient's face is turned up toward the anesthetist and surgeon at about 45 degrees. The operating table is raised as high as it will normally go, or is placed on 4 inch blocks, and is tilted about 15 or 20 degrees. To complete the essentials of this position, the authors have made a head rest that will fit any table. It is adjustable by a vertical worm screw and handle below, may be extended from the table for adults, and also moves laterally, following any movement the patient may make. Being adjustable, therefore, in three directions it is quite safe, and it is suitable also for bronchoscopic examinations. A Crowe-Davis mouth-gag is used.

**Treatment of Surgical Tuberculosis.**—Jerábek considers the types of surgical tuberculosis that present grave obstacles to surgical intervention. To this group belong para-articular foci of tuberculosis. Operation is indicated in such cases only when the roentgenogram shows distinct signs of a circumscribed cavity. Sequestrums, especially the larger ones, have a tendency to spontaneous evacuation; only the smaller ones may be absorbed. That is why fistulas are often found near such a focus. In treating these and other complications, followers of conservative trends were satisfied by the application of a plaster-of-paris bandage with an aperture for the fistula, through which the dressings were changed. The author believes it necessary to eradicate foci even if secondary infection has taken place or if the abscess has not yet broken through, and that conservative treatment is too prolonged and too passive and does not prevent the possibility of eventual extension into the joint. He has the patient prepared in the customary manner and a wide operating surface is disinfected with tincture of iodine. If there are no fistulas, the foci are incised and eradicated. After removal of the diseased tissues, the cavity is tamponed with gauze moistened with physiologic solution of sodium chloride. After the hemorrhage has been stopped, the cavity is dried and filled with sterilized petrolatum. Suture of the skin is but partial, so that the secretion may drain away. If no fistula is present and there is only an abscess, it is opened and the cavity is scraped with a sharp spoon and filled with petrolatum. Petrolatum itself drains so efficiently that it can be used even in those cases in which the cavity has had a secondary infection. The use of petrolatum alone does not

require redressing of the wound, since, in the process of healing, the petrolatum is forced out. Therefore the bone is entirely unmolested, which is desirable for healing. Filling the cavity with petrolatum is proper even if no fistulas are present. The principal reason for filling the cavity is to replace the defect with material similar to osseous tissue which, through osteoblastic activity, will supply the basis for a quicker compensation of the defect. The filling is supposed to restore the disturbed stability of bone and at the same time to act as a preventive to infectious agents in the cavity. Fillings that contain disinfecting materials represent foreign bodies which irritate and cause reactions that end in elimination. Petrolatum fillings keep the cavity from filling with blood, preventing the increase of microbes on favorable ground. Bone tissue bears petrolatum exceedingly well because of its neutrality and nonirritability.

**Dislocation of Elbow.**—Crosby feels that, regardless of the type of dislocation in an elbow, four-direction traction minimizes injury to the tissues around and in the joint, thereby reduces the amount of postreduction swelling and pain and shortens the period of convalescence. The patient is placed on a stretcher with a folded sheet around the chest. The sheet is then tied or pinned to a crossbar on the opposite side of the stretcher. This fixes the chest and gives countertraction. A 4-inch muslin bandage is placed around the arm above the elbow. This bandage is tied so that it forms a loop, the lower end of which is about 6 inches above the floor. The foot is placed in this loop for traction downward. A similar bandage is placed around the forearm with the elbow flexed at 90 degrees and is tied behind the operator. The patient's wrist is grasped with the operator's left hand, thus producing traction upward, and the operator's right hand is free to manipulate the elbow joint. The patient is anesthetized, and, when muscle relaxation has been reached, the operator gives traction in four directions by leaning backward, by pressing downward with the foot through the loop in the bandage, by pulling upward with the left hand, and with countertraction across the chest. The dislocation in the elbow joint is easily reduced with a minimum of injury to the joint.

**Neonatal Pneumonia Due to Staphylococcus Albus-Haemolyticus.**—Conklin calls attention to an epidemic, in the nursery of an obstetric department of a general hospital, that was characterized by pustular skin lesions with fulminating respiratory infections. Multiple abscesses in the lungs of eleven fatal cases were found with the presence of Staphylococcus albus-haemolyticus. An organism obtained from one of the patients was injected into an animal in which quite typical lung lesions were found later. The presence of pustular skin lesions followed by respiratory involvement suggests that the mode of conveyance of the organism was through the blood channels to the lung and not by droplet infection. Widely fluctuating temperature reaching as high as 106 F. aided materially in the spread of infection. Publicity through the reporting of nursery infections when they occur cannot fail to bring rewards in the building of barriers against further spread and repetitions. The Dick aseptic nursery technic should be widely known and employed. It may be of importance to have nurseries adjacent to the obstetric department under the care of a pediatrician; eliminating the presence of the various obstetricians would numerically reduce the possible avenues of infection.

**Congenital Dislocation of Hip.**—Van Gorder presents the experiences of the orthopedic staff of the Massachusetts General Hospital with congenital dislocation of the hip. During ten years there were fifty-eight cases, representing seventy-three dislocated hips. Of these, only forty-six patients, comprising fifty-five hips, could be followed to the end result. The treatment of these cases consisted in closed reductions, open reductions, open reductions with shelves and shelf operations alone, depending on the nature of the case. Traction of the Hoke type or by Kirschner wire has been used both before and after reduction in about one half of the open reduction cases. As a rule, closed reduction has been reserved for children less than 5 years of age unless special contraindications were apparent. Open reductions have been performed in children more than 5 years of age and in younger children when the closed method had failed. In the series of open reductions, a shelf operation was added only in those cases that exhibited an incompetent acetabulum. "Shelf operations alone" were performed in adults and in those children whose hips obviously could not be reduced without great trauma. In such instances the femoral head was allowed to remain in the false acetabulum. Following closed reduction, it has been the custom to immobilize the hip in its most secure position of reduction for a period of about six months and then gradually, in successive stages, to allow the leg to assume its normal anatomic position, the entire period of plaster retention not exceeding from nine to ten months. The period of fixation in plaster should be much shorter after open reduction than after the closed method, the immobilization period being regulated according to the needs of the individual case. Of the sixteen closed reductions ten hips showed excellent (perfect clinical result) end results, four hips were classified as good (slight limp but excellent clinical result) results and two hips showed a fair (definite restriction of motion) result. Of the fifteen open reductions only one hip was rated as an excellent result, three hips were rated good, five hips fair and four hips poor (small range of motion), and two hips resulted in bony ankylosis. Of the eight hips that were treated by open reduction and a shelf, no single case has been recorded as an excellent end result. Two hips showed good end results and one hip a fair result, two hips were rated as poor and three resulted in bony ankylosis. Of the sixteen hips that were treated by a shelf operation alone no cases were considered excellent, but eight hips were recorded as good end results, four were considered fair and four had poor end results. In summary, good functional results were obtained in 88 per cent of the closed reductions, in 27 per cent of the open reductions, in 25 per cent of the "open reductions plus shelves" and in 50 per cent of the cases having shelf stabilizations alone.

**Syndrome Resembling Angina Pectoris.**—A case of paroxysmal cardiac pain, somewhat resembling angina pectoris, is reported by von Hofe and Eigen in a girl 8 years of age, in

whom the chief subjective symptom was the attack of anginoid pain. The pain was always associated with a period of syncope and accompanied by various vasomotor phenomenon (sweating, flushing, blanching of face). She has thus far had numerous attacks. The patient has a chronic rheumatic heart disease. In practically all the reported cases there is a severe degree of chronic rheumatic heart disease. The patient has been under constant observation for two and one-half years. During this entire period the physical observations and roentgenologic studies of the heart, as well as the electrocardiographic examinations, showed no evidence of any appreciable change in her cardiac status. She has had quite a number of "seizures" of varying intensity occurring at varying intervals, some of which were precipitated by emotional excitement and others by a moderate degree of physical exertion. At times there was no evident precipitating factor (the attack occurring while she was asleep). During the patient's stay in the hospital, it was suggested that hypoglycemia should be considered a possible cause for the patient's symptoms. Increasing quantities of insulin were given, 5, 8, 12, 15 and 18 units, and in no instance was an attack precipitated.

**Differential Diagnosis of Silicosis.**—Ornstein states that the diagnosis of silicosis should not be made unless there is a definite history of exposure to silica dust. An overseer of a group of street excavators made claim for compensation because of a pulmonary tuberculosis complicating silicosis. There was no question with regard to the diagnosis of pulmonary tuberculosis. The difficulty arose with the diagnosis of the silicosis. There was bilateral upper lobe cavitation with a bronchogenic seeding down both lungs. The diffuse bilateral bronchogenic tuberculosis was interpreted by a group of physicians as silicosis. With a history of short duration of exposure and very little chance for concentration as would occur in the open streets, the diagnosis of silicosis should have been discarded. Furthermore, in reviewing the serial roentgenogram it was noted that the maximal intensity of the bronchogenic seeding was in the first roentgenogram. From then on, the serial roentgenogram revealed a slow resolution of the diseased areas. Resolution does not occur in silicotic nodules. The nodule in silicosis either remains stationary or progresses. Whenever there is evidence of pulmonary fibrosis, one must obtain a detailed history of previous occupation. A clerk in charge of the pay roll of a gang of rock drillers was roentgenographed. He never had been exposed to silica dust. A roentgenogram of his chest was interpreted as advanced silicosis. He did have spasms of coughing and expectoration, and he became alarmed because of the diagnosis of silicosis. On examination it was found that he had fibrosis in both lower lungs secondary to nasal instillation of as much as an ounce of liquid petrolatum a day. When there is sufficient occupational history, the roentgenogram becomes the most important examination for the diagnosis of pulmonary silicosis. In the early stages of silicosis, the root and bronchial accentuation can be easily simulated by bacterial infections or by other irritants. In advanced stages of silicosis there is great difficulty in ruling out tuberculosis. The con-

fusion comes from the dense areas for which various investigators have used the term "infective silicosis." In fifty-nine cases collected at the Metropolitan Hospital a diagnosis of pulmonary tuberculosis was made, and the patients were transferred without a suspicion of an occupational disease. In this group of fifty-nine patients the diagnosis in thirteen was far-advanced pulmonary tuberculosis with sputums negative for tubercle bacilli. It is this type of case that causes so much confusion with regard to the association of tuberculosis and silicosis and is usually labeled silicotuberculosis. This group cannot be classified as clinical tuberculosis, with sputum negative for tubercle bacilli, any more than one could label other patients with fibrotic tissue in the lung and with negative sputums as tuberculous.

**Renal Function Following Trauma of Kidney.**—Powers believes that the intelligent treatment of patients with traumatic lesions of the kidney depends on a knowledge of the degree of function which the organ may be expected to regain when healing is complete. There is an occasional case in which the damage is so extensive and the hemorrhage so severe that immediate operation, preceded by transfusion and other supportive measures, is a necessity. The majority of patients, however, do not require such radical and heroic treatment. Hemorrhage from the kidney, pain, tenderness and spasm may persist for days and be followed by rapid and complete restoration of renal function. Two clinical cases of renal trauma, one moderate and one severe, have been reported. The ability of the injured kidney to excrete phenolsulfonphthalein and the pyelographic appearance of the renal pelvis promptly returned to normal in the first case. In the second instance the recovery was less rapid but equally satisfactory. Experimental observations have been submitted which demonstrate the prompt return of normal function following renal trauma of moderate severity in rabbits with only one kidney. Severe and extensive injury after unilateral nephrectomy is followed by death. Severe trauma of one kidney, if the opposite organ is intact, produces no significant change in total renal function, measured by the fractional and total excretion of phenolsulfopphthalein and the nonprotein nitrogen of the blood. If the normal kidney is removed after the critical, immediate posttraumatic period is over, the injured organ will recover sufficient function to maintain renal activity at a normal level. The clinical reports and experimental data suggest that the majority of patients with unilateral renal trauma may be treated conservatively with the expectation that the injured kidney will recover sufficient function to be a useful and serviceable organ.

**Bacterial Toxemia.**—Solis-Cohen asserts that toxins elaborated by the bacteria in a focus of infection may, without producing pathologic changes, give rise to symptoms similar to those occurring in organic disease. The symptoms simulate

those present in disease of the circulatory, gastro-intestinal, nervous, locomotor, lower respiratory and other systems, leading on the one hand to the diagnosis of systemic disease and on the other to a diagnosis of neurasthenia, hypochondriasis, and the like. Examination fails to confirm the suspicion of organic disease suggested by the symptoms but discloses focal infection. Every possible focus of infection must be examined bacteriologically by a method of culture that not only discloses all the germs present but, in addition, determines their infectivity for their host. Such a method is the pathogen-selective method, which in chronic and focal infection selects the causal organism from a mixed culture. It is necessary to distinguish between symptoms due to bacterial toxemia and those due to systemic disease, psychic disturbances, nonbacterial allergy, endocrine dysfunction and lack of vitamins. Treatment consists in the complete removal of the focus of infection, which includes the destruction of the infecting bacteria and the rendering innocuous of their toxic products through the artificial stimulation of specific antibody production. The latter is accomplished by the administration of a potent vaccine, such as the pathogen-selective vaccine, which contains both the infecting microbes and their soluble exotoxins. The initial dose of pathogen-selective vaccine depends on the result of graduated intracutaneous tests. Subsequent doses are based on the general, focal and local reactions to the preceding dose. The interval is determined by the character of the reaction to the last dose.

Chemotherapy of Malaria. S. P. James, London, England.—p. 567.

**Neurologic Disturbances in Pregnancy.**—In their investigation of seventy-eight cases of pregnancy, Roxas and his associates observed hypocalcemia associated with neurologic disorders in fifty-eight. The symptoms presented were paresthesia, cramps, muscular twitchings, local edema, chest oppression, backache, brittleness of the nails, dental caries, thinning of the hair and muscular weakness. That abnormal symptoms are caused by hypocalcemia has been borne out by several observers. The probable interpretation is that there is an initial disturbance in the calcium and phosphorus balance, so that nervous symptoms begin to appear even before actual hypocalcemia exists. Then, if there is further disturbance, the calcium begins to fall and the train of symptoms makes its appearance. This disturbance is due either to a diminution of calcium or vitamin D supply or to a parathyroid insufficiency; and, from the behavior of the phosphorus, it seems that the parathyroids are also at fault, just as is the country's diet. The association of beriberi and pregnancy is another question of importance to the clinician. The result of the authors' analysis of six cases shows that in beriberi the range of calcium is normal. A further study of seventeen cases of beriberi in the nonpregnant state was conducted and the result was likewise a normal curve for the calcium concentration. If this observation is borne out in further studies, a differentiation of the two conditions in pregnancy may be aided by laboratory examinations. Other conditions which gave similar symptoms were a case of pulmonary tuberculosis and one of cardiac failure. The occurrence of neurologic disturbances in a pregnant woman should put the clinician on his guard. Avitaminosis is a treacherous enemy of such a patient. The symptoms may be so slight and unapparent as to be overlooked, only to manifest themselves disastrously after delivery. Patients who gave no symptoms or history indicative of beriberi went through a normal delivery and twenty-four hours later were found with bilateral paralysis of the legs or with footdrop and handdrop. Such patients may or may not recover. Routine calcium therapy of an antepartum case in the absence of a real indication may do more harm than good. Undue calcium administration to the expectant mother often causes serious complications during labor. The head of the fetus fails to

mold, probably because of premature calcification; labor becomes unduly prolonged and, oftentimes, must be terminated by cesarean section.

**Resistance of Escherichia Typhi and Coli-Aerogenes to Chlorine.**—Heathman and her co-workers found that the disinfecting action of chlorine in treated waters is variable within limits. The time required for chloramine and for chlorine in some instances to kill strains of Escherichia typhosa and members of the coli-aerogenes group is appreciably greater at low temperatures than at room temperature. There is considerable variation in the resistances of freshly isolated strains of Escherichia typhosa and of members of the coli-aerogenes group to the disinfecting action of chlorine and chloramine. Certain recently isolated strains of Escherichia typhosa exhibit a greater resistance to the disinfecting action of chlorine and chloramine than do old laboratory strains that have been grown on artificial mediums for a number of years. There is a possibility of viable Escherichia typhosa persisting in waters treated with chlorine or chloramine as long as, and in some instances longer than, members of the coli-aerogenes group. These results indicate the desirability of reconsidering the significance of the coli-aerogenes group as a bacteriologic index of the safety of chlorinated water.

- \*Low Back Pain. J. G. Kuhns, Boston.—p. 131.

**Low Back Pain.**—Kuhns discusses the accumulated data on low back pain, from which he concludes that backache manifests itself as either local or symptomatic pain. Local pain is due to injury or disease of the spine and pelvis, or their supporting structures. Of injuries, sprains of the muscles, ligaments or fascia are most common, with faulty posture frequently acting as a predisposing cause. Of diseases of the spine, rheumatoid arthritis and osteo-arthritis are most common. In symptomatic backache the cause is usually a disease or functional disturbance in the abdominal or pelvic viscera, the pain being transferred to the cutaneous area of the nerve branches that supply the viscus affected. The differential diagnosis is often tedious. It must be determined whether the pain is local or referred. In referred pain, pain alone is present. Muscle spasm, tenderness and limitation of motion in the lower part of the back are indications of a lesion in that portion of the spine or its contiguous structures. Several diseases may be active at the

same time in producing low back pain. This not unlikely possibility requires that a careful physical examination be performed as well as a systematic examination of the spine and its accompanying neurologic structures, with such roentgenograms and laboratory data as may be indicated in each case. Treatment must be comprehensive. One must remember that the patient is an individual with a visceral, neurologic or spinal lesion. The patient's fears and worries as well as his adjustments to difficulties must be considered. Nothing should be left undone that will add to his health and hasten recovery. Treatment should be sufficiently long, in the realization that the processes of repair usually take place slowly, and all factors that may aid in preventing a recurrence of low back pain should be considered.

Medical Annals of Arizona: Health Among the Navajos. S. J. Tillim, Amityville, N. Y.—p. 355.

**Prevention of Chronic Sinusitis.**—In the main, Ashley believes that the predisposing causes of chronic sinusitis can be placed in four general groups: physiologic effects, malformation of the structural framework of the nose, allergic tendencies and infections. By physiologic effects she refers to unbalanced diet, glandular dystrophies, metabolic fluctuations, excessive use of alcohol and tobacco, swimming and diving, bad ventilation, lack of sunshine and generally poor living conditions. Under malformations must be included hypertrophied tonsils and adenoids, deviated and malformed septums, enlarged turbinates, traumatic abnormalities, obstructing tumors and atresias. Allergy is an important etiologic factor in chronic sinusitis. There is a definite reason for the seemingly great increase of allergic children; namely, the substitution of various formulas all using the cow, the goat or the donkey instead of the mother for the source of food supply in infancy. There is little doubt that allergy and sinus disease frequently do go hand in hand, and, whenever this condition does exist, any treatment of one without treating the other will surely fail; and one must be particularly on guard against too active surgical treatment without the counsel of the allergist. Inflammations of the sinuses are practically all of bacterial origin; irritation caused by trauma without superimposed infection is transient. The common cold is the most frequently given etiologic factor in chronic sinusitis. Every acute head infection is potentially a chronic sinus infection. The general management of a patient suffering with a cold should be with the internist or the pediatrician, but the local treatment certainly should be left to the rhinologist. The author is of the opinion that all colds in their primary stage are allergic manifestations, that the allergy develops because of a filtrable virus made active by the failure of the body to accommodate itself to unfavorable climatic and environmental changes, that the purulent stage is due entirely to secondary invaders, and that any serious complications are due to these secondary invaders.

\*Blood Stream Infections of Kidney. H. Cabot.—p. 235.

Trigonal Loop Traction in Suprapubic Prostatectomy: New Technique. N. Lumb.—p. 257.

**Blood Stream Infections of Kidney.**—Cabot considers blood-borne infections of the kidney and chiefly those caused by the pus-producing cocci. Various of these cocci may be found in otherwise normal urine of patients with peripheral infections, such as boils, carbuncles, septic wounds and acute infections of the upper part of the respiratory tract. To investigate the latter point more closely, forty-six patients with acute inflammatory processes about the mouth, throat and ear were studied. The group was selected from patients who had a urine normal to ordinary tests and who had some fever but no signs or symptoms suggesting an infection of the kidney. The urine was studied by smear and culture, the smear being made from urine centrifugated for a considerable period at high speed. Of these forty-six cases, thirty-two showed organisms in the smear and eighteen in the culture. A group of ten control cases, of persons apparently normal, showed a negative smear in all. In two there was a positive culture showing streptococci. The pus-producing cocci appear in the urine early in the disease; they disappear as a rule in a few days, though occasionally persisting for several weeks in an otherwise normal urine. The lesions are primarily cortical and medullary. They tend to coalesce with the production of massive abscess, usually show early and marked perinephritis, and often go on to perinephric abscess. Besides the classic methods of diagnosis, stress is laid on the value of roentgenography in the diagnosis of these cases. Clouding or obliteration of the shadow of the psoas muscle is generally discoverable in perinephric abscess by modern methods. Scoliosis is not rare but is a rather late sign. Limitation of the motion of the diaphragm on the infected side as studied by the fluoroscope is more important than the literature would suggest. Pyelography both by the excretory and the retrograde method is of extreme value. This will give precise information as to the development of massive abscess by showing deformities of the calices. It will also be of much value in showing displacement of the kidney by perinephric abscess, sometimes at an early period. Stress is laid on the value of limitation of the normal mobility of the kidney due to the early development of perinephritis, often in the absence of perinephric abscess. Observations are reported, showing diminished visualization of the infected kidney as seen in the excretory program. Indications for operation are the fulminating type of infection; the widespread infection of the kidney in which the patient seems unable to control the disease, as shown by the development of anemia and failing general conditions; massive abscess of the kidney as shown by the pyelogram, and perinephric abscess. Nephrectomy is indicated in the fulminating cases, nephrectomy for widespread infection, but without massive abscess when the patient is losing ground, decapsulation and drainage for cases with well localized massive abscess, and exploration for perinephric abscess. If the pyelogram shows no evidence of massive abscess or evidence of deformity of the pelvis, simple drainage is indicated; if there is perinephric abscess and evidence of massive abscess, the abscess must be drained and the kidney explored in the region indicated by the pyelogram, and, for perinephric abscess of long standing, drainage of the abscess alone is indicated in the first instance.

\*Traumatic Edema: Pitfall in Physical Medicine. L. C. Hill. p. 623

**Traumatic Edema.**—Hill says that the circulatory, lymphatic and sympathetic nervous systems are involved in the production of traumatic edema. The breakdown of the normal

mechanism of fluid interchange is maintained by abnormal impulses from the higher sympathetic centers by way of the long reflexes, and these in their turn depend on irritating afferent stimuli from the damaged tissues, now distended with lymph. The intense bony atrophy may be due to a state of chronic venous congestion, the obstruction to the venous return following extreme distention of the part with lymph. The operation of sympathectomy, which by dilating the vessels might be expected to aggravate the situation, actually produces its beneficial effect by suppressing the long reflexes from the higher sympathetic centers. It is probable that immobilization combined with elevation, by relieving tension and promoting complete muscular and ligamentary relaxation, may modify the afferent impulses to the sympathetic ganglions. Thus a gradual toning down of the abnormal efferent influences responsible for the maintenance of the edema takes place. The successful performance of a sympathectomy probably effects its cure by a similar action. In an established case early immobilization with elevation and complete rest will not only greatly curtail the period of incapacity but prevent the resultant fibrosis. The application of physical therapy at any period other than in the late stages is unjustifiable.

**The Histidine Treatment of Peptic Ulcer.**—Barry and Florey endeavored to test Aron's theory by experiments on cats and pigs, using the operation of experimental Meckel's diverticulum devised by Matthews and Dragstedt as a basis on which to test the efficacy of histidine. There is no interference with digestion in this operation. To examine more critically the value claimed for histidine, some of a series of cats operated on in this way were left untouched and others were given daily injections of histidine. The treated cats were each given 0.5 cc. of a 2 per cent solution of histidine monohydrochloride subcutaneously. The injections were begun on the third day following operation and continued daily till the death of the animal. Of twenty-two cats not treated with histidine, twelve died early (four from hemorrhage, three from peritonitis, two from snuffles and three from unknown causes). Nine animals lived twenty days or more after operation and developed peptic ulcers, all in the ileac loop opposite the anastomosis into the pouch. Microscopic examinations of four ulcers showed that they resembled in every way a typical chronic peptic ulcer. Of the thirty-four animals treated with histidine, twenty-five died early. The other nine lived eighteen days or more and five died from hemorrhage or peritonitis. The combined results of the experiments on pigs and cats show that histidine was incapable of preventing ulcer formation when this was caused by the action of unneutralized gastric juice on intestinal mucosa. A review of the clinical use of histidine demonstrates the difficulty in judging the therapeutic value of any drug used in treating peptic ulcer. Despite the favorable reports that have been reviewed, there is still no proof that histidine has any specific action on peptic ulcer.

**Results of Histidine Treatment of Peptic Ulcer.**—Since February 1934, Bulmer has given daily intramuscular injections of twenty-one doses (5 cc.) of histidine to 126 patients who

presented themselves at the outpatient department suffering from gastric or duodenal ulcers. A follow up was made of ninety-two patients who had been rendered symptom free, and eighty-two were traced, from which it seems obvious that ambulatory treatment with histidine has as good an effect as ambulatory treatment with a diet-alkali regimen. Both hematemesis and perforation have occurred during treatment. Only one third of the patients remained symptom free after an average period of sixteen months. Deep, callous ulcers on the lesser curvature have not been influenced favorably; some have apparently healed, as evidenced by freedom from symptoms and a normal roentgenogram, but relapse has been frequent with reappearance of the ulcer crater. While these cases are not common, some are successfully treated by radical surgical procedures, but in others technical difficulties make this impossible and they remain an unsolved problem. The author's conclusion is that histidine should be used not as an alternative but as an adjunct to the usual methods of diet and alkali, so that the patient may have the known advantages of the latter with the addition of the probable advantages of the former. It is best to order a simple diet with "feeds" between meals, with alkali or antacid, to insist on reasonable after-treatment and to repeat the injections should a relapse threaten. The treatment should be reserved for simple, uncomplicated ulcers, for patients with ulcers of the stomach and for those in whose case the usual methods have failed. Ambulatory treatment under these conditions appears to be safe and effective, and there do not seem to be any toxic incidents, as none were encountered in more than 3,000 injections.

Massive Pulmonary Embolism. J. B. Cleland.—p. 329.

**Intracranial Injuries of the New-Born.**—Nattrass declares that many infants who survive have intracranial injuries. The greater number will have no more than small hemorrhages and small tears of the tentorium cerebelli or edema of the adjacent parts. But others may survive with extensive intracranial injuries; and he has seen infants who have survived for eight days in whom postmortem examination revealed an old hemorrhage as big as a fist and extensive damage of the dural septums. In those who survive, the clinical signs and symptoms are neither uniform nor characteristic. They are usually present at or soon after delivery; but occasionally the symptoms do not appear for three or four days, because bleeding continues slowly for the first few days and the accumulation of blood eventually becomes great enough to produce signs or symptoms. The infant is usually born in a condition of asphyxia, generally of the pallid type, and is often difficult to resuscitate. If respiration is established, it may be noticed in the next few days that the respirations are slow and irregular, and there are often attacks of cyanosis. Often the child is noticed to have convulsions, neck rigidity, perhaps unequal pupils, and strabismus or nystagmus. A most important point is that the sucking reflex is often impaired. In the majority of cases of intracranial injury, hemorrhages both of the infratentorial and of the supratentorial types occur, so that it is not usually possible to decide where the hemorrhage is likely to be. The most important thing is that, as long as the obstetrician thoroughly appreciates his responsibility for the early recognition of the injuries and carefully observes the new-born infant immediately after birth and during the first few days, he will probably not miss the infant's suffering from these injuries and so will be able to carry on with treatment immediately. To confirm one's sus-

picians, lumbar puncture not only determines the diagnosis but is of definite therapeutic value; for as the result of the relief of the increased intracranial pressure by lumbar puncture, the danger of later impairments can be lessened and even avoided. Practically the only treatment in the resuscitation of the newborn is to remove any mucus from the throat by means of a mucus catheter and to encourage attempts at respiration by gentle traction on the tongue with tongue forceps at the rate of about twenty pulls per minute, together with the injection of a cardiorespiratory stimulant. Should the infant attempt to breathe, carbon dioxide may be of some value. If the infant does not respond to this gentle treatment within a minute or two he must be considered as having potential brain injuries, and small hemorrhages may soon prove fatal if vigorous manipulations are resorted to. While the tongue manipulations are being carried out, the infant should be left in a warm bath or in warm blankets. If the infant with injuries responds to this treatment, it should then be placed in a warm cot, preferably in a darkened room. It should not be put to the breast until all apparent danger is over but should be fed by bottle, or by pipet if the sucking reflex is impaired. Attacks of cyanosis may be treated by the use of oxygen and carbon dioxide.

Destruction of Bilharzia Parasites of Man. F. G. Cawston.—p. 608.

**Is Sympathectomy Justified?**—Verster believes that sympathectomy should be resorted to only when all the conservative methods have failed. It is useless to expect any result by performing lumbar ganglionectomy, e. g., in chronic constipation, because such good results are obtained in Hirschsprung's disease. From the "sympathetic" point of view these diseases are totally different and sympathectomy must not be expected to perform miracles. When the choice has been correctly made a preoperative test should always be performed first, with operation only in cases showing a rise of skin temperature above 5 degrees. In causalgia these tests have no value, and every other possible cause must be excluded for this condition. Sympathectomy is at most only a symptomatic treatment and not a cure. In relieving the vasoconstriction, the progredient calcification in the larger vessels or the obliterative arteritis is not cured. Advantage can be derived from ganglionectomy or sympathetic block carried out before or immediately after operations or injuries that involve obstruction or threatened obstruction to large arteries of the extremities. Only when these principles are adhered to may one expect some consistency in the results and thus establish sympathectomy on a surer basis whereby it may regain much of the credit it has lost in the past.

**Air Injections in Epilepsy.**—Delagenière discusses four cases of epilepsy in which air injections were given by the lumbar route. In two instances the aim was therapeutic, and in two diagnostic only. In three cases the generalized attacks of known or unknown traumatic origin completely ceased after the injection and in two of these disappeared permanently. In discussing these observations, the author states that it seems that in jacksonian epilepsy the attacks can be favorably influenced by the injection of air into the subarachnoid spaces, while in essential epilepsy attacks cannot be influenced in any lasting fashion. He cannot advance a satisfactory hypothesis to explain these results. Nevertheless, the innocuousness and simplicity of the treatment deserve recognition and further study.

### Gynécologie et Obstétrique, Paris

34: 177-256 (Sept.) 1936

- "Aigrette" of the New-Born. Fruhnscholz and Hartemann.—p. 177.  
\*Tuberculosis of Uterine Body of Hemorrhagic Form. N.-C. Lapeyre and H.-L. Guibert.—p. 182.

Thoracoplasty and Pregnancy. A.-I. Blisnjanskaja and A.-I. Lasarevitch.—p. 207.

**Tuberculosis of Uterine Body.**—Lapeyre and Guibert report a case of tuberculosis of the body of the uterus. The principal symptom of the patient, who was 36 years of age, was uterine bleeding for about one year. The first diagnosis was fibroma, and treatment by roentgen rays was proposed. Later, hystero-graphy revealed the existence of a congenital malformation giving the uterine cavity a bicornate aspect and showing an irregular lacunar defect of the mucosa. Subtotal hysterectomy was later performed. The histopathologic analysis of the uterus and tubes showed the presence of giant cells and caseous tubercles. Miliary infiltration of the uterine muscle with true infarction by tuberculous granulation was seen. The case reported was of considerable interest from the standpoint of diagnosis and of the use of x-rays in the diagnosis. The authors believe that tuberculosis of the uterine body is not as rare as is often considered.

**Ascension of Trichomonas Vaginalis.**—Hees discusses the part played by Trichomonas in inflammatory lesions about the vagina. In one patient the anemia, loss of weight and abundant menstruations were due to Trichomonas invasion. Eventually a chronic purulent salpingitis was produced. When Trichomonas reaches the upper portions of the genital tract, it never causes temperatures above 39 C. Generally the temperature oscillates between 38 and 38.5 C. for several days and thereafter returns to normal or below. The author concludes from his study of this case and of others that it is possible to demonstrate Trichomonas vaginalis microscopically in ovarian cysts, chronically inflamed tubes, the placenta, the peritoneum, the endometrium, the blood, the male spermatic fluid and the internal organs of the embryo. Trichomonas is as common as the gonococcus and its specific ability to produce local and general tissue injury is far from negligible. Initially, Trichomonas involves only the vagina, but it frequently causes ascending disorders, characterized in various ways. It is impossible to deny its toxic effect on the central nervous system and the general state of the patient. As a rule, however, it may be completely cured.

Positional Treatment in Course of Artificial Pneumothorax. J.-P. Lelong and E. Peyret.—p. 1502.

**Local Immunity of Intestine.**—Besredka discusses the nature of immunity. From the standpoint of experimental studies on local immunity, he believes that the mouse is too small and the monkey too expensive to serve as adequate experimental animals. In most of his tests, therefore, the rabbit has been used, and the intestinal resistance decreased by the use of bile. In this way it is possible to use the rabbit in testing the effectiveness of oral vaccination with typhoid, paratyphoid bacilli and others. Experiments of this nature added to a considerable list of epidemiologic statistics indicate that local vaccination of the intestine, which aims at the specific reinforcement of natural local immunity, is based on as solid ground as is vaccination by subcutaneous means. Even though oral vaccination in man still has some disadvantages compared with subcutaneous vaccinations, it also offers the advantage of localized tissue immunity over the latter.

### Practical Value of Serum Diagnosis in Gonorrhea.

Schaaf and Burekhardt's clinical experience with the complement deviation test in gonorrhea convinced them that a positive reaction may be obtained in a certain percentage of both uncomplicated and complicated cases of gonorrhea. A certain parallelism appeared to exist between the strength of the reaction and the clinical course in the cases of gonorrheal complications but not in the uncomplicated cases. However, even in the former there were cases in which there was found a great divergence between the clinical course and the degree of retardation of the hemolysis. The authors are at a loss to explain this discrepancy as well as the fact that in some instances they had obtained a negative complement absorption test in the presence of gonococci, or a positive test in their absence. Serologic test for gonorrhea is indicated in arthritis of uncertain origin and in adnexitis, epididymitis and prostatitis in which there is a suspicion of gonorrheal etiology. The reaction is of less value in cases of urethritis of indefinite etiology, cervicitis or proctitis. It is well to remember in this connection that the gonorrheal complement deviation reaction makes its appearance not infrequently from two to five weeks after the acute onset of the complication and under certain conditions may become once more negative after a few days or weeks. The test therefore must be performed at the proper time and frequently repeated. A negative reaction does not rule out gonorrhea. The reaction in some cases may be positive for only a short time. The cure of genital gonorrhea cannot be determined by a negative test in view of the discrepancy between it and the finding of the gonococci in the genital secretions. A positive reaction is a strong argument in favor of the gonorrheal nature of the condition. The microscopic search for gonococci, however, must not be omitted. A positive gonorrheal complement deviation test in the absence of gonococci is merely suggestive and assumes a decisive value when considered along with a characteristic history and clinical symptoms. The test is of no value in patients treated with gonorrheal vaccine, since a single injection of it may produce a positive deviation. The authors conclude that the gonorrheal complement deviation reaction is helpful in diagnosing obscure cases of gonorrheal complications when considered in conjunction with the clinical signs and bacteriologic study.

Transplantation of Ureter into Bladder: Further Experiments. D. Ciddio.—p. 506.

Mens Agitat Molem: Study on Pathogenesis of Peptic Ulcer. B. Schiassi.—p. 514.

**Thiemia in Surgical Diseases.**—The average amount of normal thiemia found by Bracci is 36.4 mg. per thousand cubic centimeters of blood. A fraction of 24 per cent of the total amount of sulfur in the blood is neutral sulfur, which is the most important and constant fraction. Thiemia increases in surgical diseases, especially in peritonitis. The variations include the several fractions of total sulfur, especially neutral sulfur. The changes result in a diminution of the coefficient of oxidation with parallel increase of the neutral sulfur-total sulfur ratio. The changes of thiemia in renal and liver diseases depend on the preservation of the functions of the kidney and the liver. The variations of the neutral sulfur-total sulfur ratio are an index of the functions of the liver. A high ratio, indicating a quantity of more than 40 per cent of neutral sulfur in the blood, shows grave alterations of the liver functions and an unfavorable prognosis. The small amount of thiemia found by the authors in surgical spleen diseases conflicts with the opinions in the literature, according to which the spleen seems to be concerned with the production of neutral sulfur. Total sulfur and the neutral sulfur fraction greatly increase in diseases associated with skin pigmentation. The increase seems to be due to latent adrenal insufficiency. Thiemia changes after operations. The changes depend on the intensity of trauma, the type of anesthesia used and the performance of an operation on organs that are concerned in controlling the sulfur metabolism or normal thiemia. Operations are generally followed by a diminution of the acid sulfur fraction and an increase of the neutral and total sulfur with resultant increase of the neutral total sulfur ratio. The changes are due to augmented autolysis of traumatized tissues, decreased functions of the organs concerned with the elimination of sulfur, especially the liver, effects of general anesthesia and the postoperative fasting. Operations on the liver or biliary tract by which the functions of the structures are restored bring immediately a high neutral sulfur-total sulfur ratio down to normal. Following splenectomy, ligation of the splenic artery and lumbosacral sympathectomy, the total sulfur and the acid sulfur fraction increase and the neutral sulfur fraction and the neutral sulfur-total sulfur ratio diminish. Following blood transfusion the total sulfur, its acid and neutral fractions and the neutral sulfur-total sulfur ratio increase. Intense increase of the ratio is followed by development of a serious general reaction, which is due to plasmatic colloid disturbances.

Chronic Appendicitis and Pseudo-Appendicitis. G. Cavina.—p. 1339.

\*Relations Between Gastric Chemism and Erythropoiesis. E. Lombardi and J. A. Cino.—p. 1343.

**Gastric Chemism and Erythropoiesis.**—Lombardi and Cino state that there is a relation of interdependence between the gastric chemism and erythropoiesis, as proved by the development of anemia following gastrectomy, the increased erythrocytosis in patients suffering from hyperchlorhydria and

gastroduodenal ulcer, and the presence of hyperchlorhydria in patients suffering from erythremia. They studied the behavior of erythropoiesis in relation to the modifications of the gastric acidity, induced in man by intravenous injections of sodium benzoate and in dogs by intravenous injections of sodium benzoate or subcutaneous injections of histamine hydrochloride. The intravenous injections of sodium benzoate induce in both human beings and dogs a simultaneous diminution of the erythrocytes and of the total acidity and free hydrochloric acid in the gastric secretion. The subcutaneous injections of histamine hydrochloride in dogs have the same results. The variations in the number of erythrocytes do not depend on an uneven distribution of the erythrocytes in the blood of the peripheral and visceral vascular territories, as is proved by the fact that the number of erythrocytes in the blood from the ear and from the heart of dogs in the authors' experiments was almost the same. The authors conclude that the variations of the gastric chemism induce parallel variations of the erythropoiesis and they admit the existence of the so-called achylous anemia and hyperchylous erythremia.

Vascular Insufficiency of Extremities: Pathogenesis and Treatment. G. Barbera.—p. 409.

Systematic Examination of Right Iliac Fossa in Chronic Appendicitis. E. Giupponi.—p. 443.

\*New Method for Preventing Postoperative Complications in Prostatectomy. P. Blasucci.—p. 448.

**Preventing Postoperative Complications of Prostatectomy.**—Blasucci states that most of the grave complications following prostatectomy are caused by sepsis. He prevents development of the latter by means of a postoperative procedure, which he describes as follows: A thick rubber tube is introduced in a pear-shaped Hagner bag at its base. Immediately after enucleation of the prostate a Nelaton catheter is introduced into the urethra. (The catheter is previously perforated with small holes through its entire length to allow irrigation of the urethra.) The tip of the Nelaton catheter is drawn out through the hypogastric wound and fixed to the apex of the pear-shaped Hagner bag. Traction is then applied to the Nelaton catheter at the urethra so that the Hagner bag enters the bladder and fits snugly in the cavity left by removal of the prostate. The bag is inflated through the rubber tube, which comes out at the hypogastric wound according to the intensity of hemorrhage. If the latter is not controlled, slight traction is made on the Nelaton catheter in the urethra so that the bag fits more closely into the cavity left by removal of the prostate. After the hemorrhage has stopped for a few hours the traction of the Nelaton catheter is released and the cannula of a Dakin drip is connected to the free end of the Nelaton catheter to allow the diluted solution of sodium hypochlorite to flow in drop by drop. In this manner the prostatic cavity is continuously irrigated and sterilized by the antiseptic solution, which then flows into the bladder and out through the suprapubic drain. Generally the patients do not like the procedure, but the results are satisfactory. The postoperative evolution is uneventful and none of the grave (sometimes even fatal) complications of prostatectomy set in. Since the procedure has been carried on by the author, sepsis has been less frequent in his cases and the time necessary for the patient to recover has been shorter than previously.

Chronic Purpura and Biliary Lithiasis: Case. R. Gernich, J. M. Palazon.—p. 2390.

\*Alkali Reserve in Depressive Psychoses. Paulina H. de Rabinovich.—p. 2393.

**Alkali Reserve in Depressive Psychoses.**—According to de Rabinovich, anxiety and depression are psychoneuroses originated in alkalosis which depends on rupture of the acid base balance due to sympathetic disturbances. She determined the alkali reserve in thirty-five patients suffering from psychoses, especially of the melancholic and anxiety types. In all cases there was alkalosis, which was more intense in cases of melan-

choly with anxiety. The author believes that her results support the theory of the pathogenic rôle of alkalosis in depressive and anxiety psychoses and points out the advisability of administering acidifying drugs and a diet aiming to control alkalosis. According to the literature (Laignel-Lavastine), the antialkalotic treatment gives promising results in controlling the mentioned forms of psychoses.

\*Cysts of Mesentery. C. Lugones and D. A. Molina.—p. 1282.

**Cysts of Mesentery.**—Lugones and Molina made a study of congenital cysts of the mesentery with especial reference to those of a lymphatic origin (serous and chylous cysts). They state that the early symptoms of congenital cysts of the mesentery are the increased size of the abdomen and the appearance of gastric disturbances, abdominal pain and a round, smooth, mobile tumor at the periumbilical region. As a rule, the condition follows a benign evolution, unless the tumor is too large or adhesions are formed. In such cases grave disturbances, especially dependent on compression of the organs and vessels, set in. In cases of gastro-intestinal disturbances of long duration the nutritional disturbances of the patient result in cachexia. The treatment is surgical. It consists in the removal of the cyst with the involved segment of the intestine. The author reports three cases of congenital cysts of the mesentery (dermoid in one case and serous cysts in two others). Two of the cases were in children. In one of the cases the tumor recurred sometime after the operation. From observations in their cases and from a review of the literature on the subject, the authors modified Donati's classification of congenital cysts of the mesentery by including in the group serous and chylous mesenteric cysts. The form and histologic nature of the cysts and the physiologic and anatomic relation between chyle and lymph prove that both types of cysts are of congenital lymphatic origin. According to the authors, congenital cysts of the mesentery are in a latent condition, owing to a special predisposition of the mesentery. The development of the cysts depends on the action of certain unknown determining factors by which the latent condition is stimulated first to evolve into the cyst formation and then to continue its growing.

Electrocardiographic Curve in Case of Myocardial Infarct. J. Espejo Solá.—p. 1073.

\*Methylene Blue in Treatment of Psoriasis. M. D'Agostino and E. Torres.—p. 1080.

**Exophthalmic Goiter and Hemorrhagic Thrombocytopenic Purpura.**—Finochietto and his collaborators report a case of exophthalmic goiter associated with hemorrhagic thrombocytopenic purpura. The development of the latter preceded that of the former. The patient was treated by a subtotal thyroidectomy and has practically recovered from hyperthyroidism. The satisfactory results persist after a year and a half. The purpura improved from both the clinical and hematologic points of view. Thrombocytopenia persists (30,000 platelets). According to the authors, their case proves that purpura is of idiopathic origin and not secondary to hyperthyroidism. In the authors' case the two diseases have a common origin; that is, both originate in a pathologic condition of the bone marrow.

**Methylene Blue in Treatment of Psoriasis.**—D'Agostino and Torres report satisfactory results in treating psoriasis with intravenous injections of a 2 per cent solution of methylene

bluc in double distilled water, a diet poor in proteins and fats but rich in vitamins, and local application of Brocq's ointment. The renal functions of the patient are previously determined, because the treatment is to be administered to persons with good renal functions or grave renal complications may set in. The injections are given slowly in doses of 5 cc. of the solution for the first one, 7 cc. for the second and 10 cc. for the remainder. They are given three times a week up to fifteen or twenty injections. The ointment, which is locally applied, consists of 1 Gm. each of chrysophanic, salicylic and pyrogallac acids, 10 Gm. each of ichthammol, tar and hydrous wool fat and 30 Gm. of petrolatum. The tolerance of the skin to the ointment is previously tested by applying it to a small area. The ointment is not to be applied to the scalp. For the latter, as well as in cases of sensitive skin, the ointment can be replaced by local applications of cade oil or any ointment containing salicylic acid. With these precautions the treatment is not dangerous. So far the authors have treated seven patients. There was recovery in two cases, improvement in four cases and failure in one case. However, the time elapsed since discontinuation of the treatment has not been long enough to assure them that no recurrences will take place.

### Monatsschrift f. Geburtshilfe u. Gynäkologie, Berlin

103: 1-124 (Aug.) 1936. Partial Index

- Fatalities from Cesarean Operations. Hüsey.—p. 16.
- \*Pathogenesis of Acute Hydramnion. G. Gaetgens.—p. 40.

**Familial Occurrence of Uterine Myoma.**—Winkler points out that, in view of the high incidence of uterine myomas, it is difficult to furnish definite proof for a hereditary transmission of this condition. Nevertheless, he decided to investigate the problem on the material passing through his clinic. He encountered considerable difficulties in that most of the women knew little about the disorders of their blood relations and the idea of tumor of the uterus is extremely indefinite in lay circles. However, he observed three sisters who required treatment for uterine myoma and they stated that their mother likewise had had a benign uterine tumor. Although at the time of operation the sisters were 37, 42 and 44 years of age, there were indications, such as repeated abortions, which indicated that uterine myomas existed long before surgical treatment was resorted to. The author further mentions a number of other investigators who have observed the familial occurrence of uterine myomas. The cases of the three sisters are important also because all three had symptoms that are characteristic for exophthalmic goiter. The search for corroborating evidence of a causal connection between myoma and goiter failed. Moreover, most patients with myoma have characteristics that incriminate hypothyroidism rather than hyperthyroidism. Consequently, the author suggests that the disturbance in the thyroid function and myoma formation are coordinated symptoms of a superimposed ovarian function. In this connection, he cites Hofmiller, who in a large necropsy material of women with myoma observed that 51 per cent had changes in the thyroid and 30 per cent had changes in the ovaries. He thinks that this furnishes an explanation of the vasolability of most women with uterine myoma, for it is well known that dysfunction of the thyroid leads to cardiac and vascular disturbances.

**Ulcerative Colitis and Pregnancy.**—Saegesser points out that diarrheal conditions, which have a causal connection with pregnancy, have been described by Seitz and by Condi. He himself observed two women who, in the course of pregnancy, developed ulcerative colitis. After describing the histories of these patients, he admits that the concurrence of the ulcerative colitis with pregnancy may be accidental. However, the fact that the bacteriologic examination was negative excludes an infectious cause and in the second case, particularly, there was evidence that the pregnancy had some etiologic significance, for the woman developed colitic conditions in her three pregnancies, and her intestinal function was normal again each time after the colitis had healed. The author thinks that the persistence of the symptoms of colitis beyond the puerperal period does not neces-

sarily exclude a causal relationship with the pregnancy, because ulcerative colitis causes anatomic changes, which frequently prove extremely refractory. The author points out that the etiology of ulcerative colitis is not yet completely explained but that a sympathetic hyperirritability is often regarded as a factor. Moreover, such a condition may readily become aggravated by pregnancy. The author suggests that the differences between the cases of colitis reported by Seitz and Condi and his two cases of ulcerative colitis are probably only a matter of degree of severity.

**Pathogenesis of Acute Hydramnion.**—Gaetgens says that the pathogenesis of hydramnion has been ascribed to various factors. Observations have proved that this anomaly of the amniotic fluid may develop in several systemic diseases of the maternal organism, such as diabetes, syphilis and renal and cardiac disorders. Acute hydramnion has been observed also after local trauma. In most, if not in all cases, twin pregnancies were involved in the cases in which a trauma preceded the development of the hydramnion. Thus it suggested itself that the peculiar circulatory conditions of such pregnancies were responsible for the development of an acute hydramnion. The author describes the histories of two cases and in the discussion, stresses once more the high incidence of cases of hydramnion in twin pregnancies. Both described cases likewise involved twin pregnancies. He emphasizes that the acute hydramnion of twin pregnancies develops as the result of the cardiac decompensation of the stronger of the two twins. But although it may be said in general that stasis in the fetal circulation is responsible for an excessive production of amniotic fluid, it is not necessarily a cardiac decompensation that forms the basis of this stasis. The anamnesis of the second case reported by the author indicates the importance of a traumatic influence.

- \*New Rapid Method for Early Diagnosis of Pregnancy. G. de Nito.—p. 1272.

**Cutaneous Cancer After Chemical Treatment of Corn.**—Busse cites a case in which a cutaneous cancer developed on the small toe of a man following the treatment of a corn with chemical substances. The toe was removed by exarticulation and the histologic examination of the tumor disclosed a cornifying squamous cell carcinoma. It remained doubtful whether the neoplasm was the cancerous degeneration of the corn or a cutaneous carcinoma that was elicited by chemical influences. At the time of discharge, the scar showed no sign of irritation, but there were slightly enlarged inguinal glands. Renewed examination of the patient after nine months for possible metastases revealed no changes on the foot but the inguinal glands were still palpable.

**Another Method for Early Diagnosis of Pregnancy.**—The pregnancy test suggested by de Nito is based on the fact that the intravenous injection of pregnancy urine results in changes in the number of leukocytes in the test animal. The author makes the test on rabbits. He determines the leukocyte number in the rabbit and then injects intravenously from 5 to 10 cc. of the urine that is to be examined. After from two to four minutes has passed, he again counts the number of leukocytes. If the injected urine is from a pregnant woman, a considerable reduction in the number of leukocytes is observable, whereas there are only insignificant changes if the woman is not pregnant. The phenomenon of the reduction in leukocytes was observable in all phases of pregnancy, even the early ones, so that the test is suited for the early diagnosis of pregnancy. The author performed this test in about 100 cases and obtained correct results in 90 per cent of them. He also investigated why pregnancy urine reduces the leukocytes and he calls attention to the considerable increase of blood pressure reducing substances in the urine of pregnant women and also to Abderhalden's hypothesis of the so-called protective ferments.

\*Is There a Period of Physiologic Sterility in Women? R. Araya.—p. 2074.  
Twelve Years' Experience with Tubal Insufflation by Means of Own Apparatus. R. Budimlić.—p. 2084.

**Diathermy of Uterine Mucosa in Menstrual Disturbances.**—Five years ago ten Berge started to treat uterine hemorrhages by applying diathermy to the uterine mucosa. He uses a bean-shaped button attached to an insulated rod as the pole that is introduced into the uterus. The heat of this pole rises to 50 or 60 C. The patient lies in the lithotomy position on the indifferent pole. The vulva and the vagina are cleansed and the cervix dilated to Hegar No. 6. The rod-shaped pole is introduced into the uterine cavity so that the insulated rod lies in the cervical canal. Then the current is closed and its strength is stepped up to 0.75 ampere. Now the pole is moved back and forth along the uterine wall. The duration of this treatment is two minutes. Care must be taken that the internal os is not touched for, if it is, there is danger of stenosis. Stenoses and obliterations are impossible in the uterine cavity, because only the upper layer of the mucosa is coagulated and a considerable layer of mucosa is preserved. After the treatment is over, the pole is not removed from the uterus until it has cooled. In some patients a paracervical anesthesia is required. However, in the majority of women the pain is not sufficient to require an anesthetic. The patients are kept in bed for one or two days after the treatment. The author employed this treatment in seventy-one women, thirty-four of whom were in the climacteric stage. In twenty-six (75 per cent) of the latter group the treatment was successful. The treatment can be combined with an exploratory curettage. In hemorrhages caused by endometritis, the method was successful in 55 per cent of the cases. In cases of myoma, no favorable permanent results were obtained. However, the method can be used even in these cases for the purpose of arresting the hemorrhage. Thus time is gained in which the patient can be strengthened before operation. The method involves no danger and is comparatively simple.

**Period of Physiologic Sterility in Women.**—Araya examined the validity of the theory of physiologic sterility advanced by Ogino and Knaus. He maintains that ovulation may take place at any time during the menstrual cycle and that a corpus luteum may likewise be present at any time. The existence of a pregravid stage on the part of the uterine mucosa is unnecessary for the nidation of the ovum. Observations on women who had only a single intercourse in one menstrual cycle proved that conception may take place at any time, even during menstruation. Results of artificial insemination prove likewise that it may be successful at any time in the course of the cycle. The survival of the spermatozoa within the female sex organs is sufficient to make possible the fertilization of a subsequently formed ovum. The life expectancy of the ovum is not definitely known, but it is assumed that it is at least two or three days. On the basis of these factors the author rejects the theory of a period of physiologic sterility in women.

When and How Should Pneumothorax Treatment Be Terminated? W. Neumann.—p. 1167.

**Posterior Lobe of Hypophysis and Thyroid.**—Peczenik and Popper direct attention to the fact that Pal observed two decades ago that solution of posterior pituitary exerts a favorable influence on hyperthyroidism. In order to gain a better insight into the functional antagonism between the posterior pituitary and the thyroid, the authors resorted to animal experiments. The tests were made on adult male guinea-pigs. In

order to determine whether solution of posterior pituitary has an inhibiting effect on the action of thyroxine, one group of animals was given intraperitoneal injections for ten days. Beginning with the sixth day, these animals as well as the controls (receiving no solution of posterior pituitary) were given subcutaneous injections of thyroxine. In the animals that had been treated with solution of posterior pituitary the action of the thyroxine was noticeably inhibited. The authors made other animal tests to determine the action of solution of posterior pituitary on the organism's own thyroid principle as well as on the secreting thyroid itself. They reach the conclusion that the inhibiting effect of solution of posterior pituitary has its point of attack chiefly on the peripheral organs. They admit that the therapeutic use of the solution in hyperthyroidism has the disadvantage that only a part of the cases respond to it and they think that this is the reason why this treatment has not been more widely employed. Nevertheless, one of the authors (Popper) resorted to solution of posterior pituitary in thirty-one cases and achieved improvement in twenty-two.

Clinical Observations on Paratyphoid B. M. F. Wassermann and E. N. Rozova.—p. 1492.

**Infections with Pfeiffer's Bacillus.**—To determine the specificity of Bacillus influenzae Pfeifferi, Smorodintsev and his co-workers made observations on 110 volunteers in whom an attempt was made to induce a direct infection. Attempts to graft the infection by placing pure cultures of the bacillus on cotton tampons in the nasal passages and rubbing the cultures at the same time into the tonsils failed. The authors then developed a method of introducing the bacilli in contact with the deeper respiratory passages by means of inhaling through an anesthetic mask into which a spray of live cultures was introduced. Most of the volunteers were hospitalized. All the 110 persons subjected to the experiment developed in from four to six hours a fairly characteristic clinical picture of a toxic infectious state. Cultures of washings from the pharynx gave a high concentration of colonies of the bacillus of Pfeiffer in the course of the following five to ten days. The incidence of the hemolytic streptococcus and the pneumococcus was not affected and remained at the same level as before the experiment. There was an increase in the blood of the specific agglutinins and the complement bodies. The clinical manifestations displayed a certain similarity and indicated a specific toxic-infectious state characterized by evanescence and rapid termination (from one to two days). Neither the subjective nor the local manifestations could be said to be characteristic of epidemic grip. All cases exhibited at the earliest moment of infection a definite leukocytosis. There was not a single case of contagion among the medical personnel or in the especially arranged experimental conditions favoring contact infection. The authors conclude that the artificially provoked infection in healthy persons by means of virulent live cultures of the bacillus of Pfeiffer is not identical with true epidemic grip.

**Etiology of Grip Epidemic of 1936.**—Smorodintsev and his collaborators separated a filtrable virus from the respiratory passages of cases of grip in the 1936 epidemic. This virus was found to be pathogenic for mice and to be identical with the virus of Smith, Andrewes and Laidlaw. The Leningrad strain on introduction into the respiratory passages of mice produced typical catarrhal manifestations and fever within twenty-four hours, and resistance to reinfection. Dilutions of the virus of 1:10,000 were fatal to mice when introduced intranasally. The virus could be neutralized by the immune serum specific for the English strain. It failed to cause infection in mice actively immunized against the English virus. The blood of convalescents from grippal infection was found regularly to contain a marked increase of virucidal elements. The serum of convalescents was capable of neutralizing 1,000 fatal doses of the virus in dilutions of 1:1,000, whereas the serum of

patients at the height of the disease could not do the same in dilutions greater than 1:10. These data support the concept of the filtrable virus as the primary cause of epidemic grip. The bacterial content of the respiratory passages in postgrippal complications showed a great increase during the first five or six days in pneumococci of the fourth type, the bacillus of Pfeiffer and *Micrococcus catarrhalis*. The study of sputum of sixty patients with grippal pneumonia showed identical qualitative characteristics with the microflora of the respiratory passages in uncomplicated cases of grip. It appears that by provoking the inflammatory processes in the respiratory passages the causative agent of grip, the filtrable virus, activates and mobilizes such microbes as the pneumococcus and the bacillus of Pfeiffer. This enormous accumulation of microbes is capable of giving rise in persons weakened by the action of virus to secondary infections, such as grippal pneumonia.

**Pernicious Anemia and Gastric Cancer.**—Following a description of the clinical history of a woman, aged 73, who first suffered from pernicious anemia which was successfully treated by means of liver therapy and who, two years later, presented the symptoms of gastric cancer, van der Sande discusses the possibility of a relationship between pernicious anemia and gastric cancer. He points out that the literature reports other instances of the combination of pernicious anemia and gastric carcinoma in the same patient, but he stresses that criticism is necessary in the evaluation of these cases. He cites some of the factors that must be considered in establishing a relationship between pernicious anemia and gastric cancer. He reaches the conclusion that as yet the number of cases of concurrence of pernicious anemia and gastric cancer is still too small to permit a definite statement regarding the relationship between the two diseases. Nevertheless, he opines that it is advisable to think of the possibility of a developing gastric cancer in patients with pernicious anemia.

**Ileitis Terminalis.**—Knapper shows that this form of ileitis is an inflammatory process of the terminal portion of the ileum, which sometimes spreads to the cecum. The clinical symptoms of this disorder become understandable, if attention is paid to the fact that the disease involves three processes; namely, ulceration of the intestinal mucosa, thickening and shrinking of the intestinal wall and a tendency to form internal and external fistulas. The pathologic diagnosis is based chiefly on the exclusion of specific infective processes in the ileum. For the clinical diagnosis, the roentgenologic examination of the intestinal tract is of primary importance. The characteristics of the roentgenogram are nozzle-shaped elongation of the cecum, irregular filling of the terminal loop of the ileum and dilatation of the afferent loop. As the best method of treatment, the author recommends ileocecal resection, which can be done during the acute as well as the chronic stage. To avoid the risk of relapse, the resection should be done in the healthy tissue. In some cases, resection in two stages is advisable. The author describes two cases of his own observation.

\*So-Called Choledochus Cyst. F. Koch.—p. 577.

**So-Called Choledochus Cyst.**—Koch says that primary idiopathic dilatation of the common bile duct is a cystic distention without demonstrable obstacle, secondary dilatation being due to an obstacle to the outflow of the bile. In his first patient, a girl aged 12, with a diagnosis of organic heart defect and acute gastro-enteritis, necropsy revealed, in addition to a three-chambered heart, the choledochus immediately above the entrance into the duodenum as a thin-walled, cystlike dilatation

the size of a hen's egg. The wall was made up of sclerotic connective tissue with occasional smooth musculature and was without a sign of mucous membrane. The form of the dilatation, normal condition of the other bile ducts and absence of any anatomic hindrance in Vater's papilla testified to an idiopathic dilatation of the choledochus. There was also complete lack of the spleen, a malformation of which only about thirty instances have been reported (Ask-Upmark). His second patient was a man aged 55. On necropsy an unusually large secondary dilatation of the entire common bile duct was found, with a maximum width of 8 cm., due to a constricting tumor in the duodenal papilla; the cystic and hepatic ducts also were dilated. The wall of the choledochus consisted of sclerotic connective tissue; mucous membrane and glands were missing. Idiopathic dilatation of the choledochus, the author says, occurs about seven times as often in girls as in boys; the oldest age reported is 56, and the average age on operation 14. The choledochus cyst varies from the size of a hen's egg to that of a man's head. The clinical picture is characterized by pain, jaundice and tumor. Pain, often the first symptom, and reported in 45 per cent of eighty-four cases from the literature, appears in attacks of varying intensity and duration, usually at longer intervals, and resembles gallstone colic. Jaundice, seen in 62 per cent of the cases, is usually intermittent, may be progressive, and is accompanied by the picture of a biliary stasis. The tumor, palpated in about 60 per cent of the cases, is an elastic, sometimes fluctuating, rounded tender resistance in the right side of the epigastrium. Diagnosis before operation or necropsy has been made in but few cases. The patient's history may allow the disturbance to be traced back to childhood. The importance of the surgeon's familiarity with the anomaly is stressed. Treatment is directed to restoring the flow of the bile and causing collapse of the cyst. The operative method advised is anastomosis between the choledochus or the gallbladder and the duodenum or jejunum, done in one or two sessions. The one-session procedure is almost always a choledochoduodenostomy. According to reviews cited, the mortality in primary anastomosis is 30 per cent, in operation in two sessions 35 per cent.

## THE ORGANIC BACKGROUND OF THE PSYCHOSES AND NEUROSES

FOSTER KENNEDY, M.D., F.R.S. (Edin.)

Professor of Neurology, Cornell University Medical College  
NEW YORK

Surely by its very nature neurology and psychiatry must pervade and be pervaded by all medicine.

Neurology must rest on and be supported by internal medicine and must in its turn be the base of psychiatry. We who study either must concern ourselves with the general field and, like Peter on the roof-top, call nothing in biologic thought common or unclear. In the past century, neurologists were busy collecting, classifying and, as their often unappreciative colleagues would say, "labeling" specimens of neural disorder. Now this work is largely outgrown and we have to dig below the surface of morbid phenomena to find the toxic or chemical or glandular origins of disease: often heavy and seemingly unprofitable labor, but work which is the very stuff of medicine and on which one day will be established a real pathology of mind. We need not pile up argument to show that neural change most often depends on changes in other tissues. Within the lifetime of many here, dementia paralytica, once regarded as a unitary disease—insanity—has been shown to be syphilis and nothing but syphilis; but most of the older men as students were instructed that this crumbling of a personality might come from overwork or exposure—presumably to the winds of Heaven!

When I was a house officer at the Queen Square, one of my seniors surmised that paralysis agitans was a neurosis with no organic or structural basis. We know now its cellular pathology and much of its infective origin. Asthma was once to me akin to the vapors of a still earlier day. Now we understand its allergic etiology and are beginning to sense the enormous part individual sensitiveness to specific protein may play in many cases of both organic and functional nerve disorder. So we must live in no ivory tower. We have to scour over and delve in the fields of internal medicine and also try to throw searchlights through the tenebrous fog of endocrinologic fact and fable.

However, while our vision of the so-called organic field has deepened and widened, we are still inclined to regard deviations of mental and emotional nature as disease-units in themselves. Surely the time has come to put away the notion that psychiatry deals just with mind-disease. This dualistic philosophy, this ecclesiastical view of man, is without biologic or medical support, and it has beset our minds and lamed our thoughts

for two thousand years. The notion of "space-empty" or "space-etheral" has today been abandoned and nature is now viewed as energy, patterned into worlds, patterned variously also for every stick, stone or bit of life on them. Man thus becomes one with his environment, which pervades him wholly and into which he extends himself hugely; born according to his manner, he holds his unique pattern as a momentary opportunity for experience, a stream of creative continuity with aim.

There has been a tendency among psychiatrists in the recent past to ignore this structural patterning of man, to divorce soma and psyche and to treat the mind as though it were Mohammed's coffin swung in the empyrean between earth and heaven, having neither structure nor fabric. Plotinus says that sensations are obscure thoughts; and intelligible or spiritual thoughts are clear sensations. Such unity of function and structure has been forgotten through a kind of blinkered specialism, so that a psychiatrist today has a sense of professional and social demotion should he deign to regard the bodily functions at all. Juvenal may have told him that his patient cannot cry "Evae Bacchus" with an empty belly, but nowadays the god can be invoked with propriety only as an unconscious compensation against an incestuous passion for a maiden aunt who keeps a milk-farm.

We talk of the modern brand of psychology as an analysis. Much of this ingenious scholasticism is so far from really plumbing the depths of mental origins that it is but figure-skating on the surface of the problem. The real problem is why does a certain person have to substitute something else for his difficulty in order to relieve his difficulty? And why does another person not have to go through that complicated procedure in order to be happy? The true problem is the nature of the play of organic forces in the individual causing the stable or unstable equilibrium of his feelings and his intellect. The difference between one individual and another is here in modern psychology only described and not explained. It's not enough to go into a picture gallery and say "I understand this picture, it is by Rubens," and "That there is by Velasquez." Mere recognition. The person who recognizes those pictures enough to christen them does not necessarily understand Velasquez, nor need he have an iota of knowledge as to how Velasquez mixed either his paints or his ideas. Just as we have not an iota of knowledge of the causes of two of the great scourges of our civilization, dementia praecox and manic-depressive psychosis. To make up for our ignorance, we rechristen them each decade in different dead languages and call it progress. We must not mistake the projections and productions for the deeper causes of those projections and productions. And the cause of the projections in the last

analysis lies there in the type and quality of both brain and body. Through sixty years, my grandfather nourished the vain hope of elucidating the problem of "fever" by the study of miles of temperature charts. Lacking a somatic orientation, an orientation primary rather than secondary, the causes of fever would never have been bared; and now we know that the fever then regarded as a primary disease entity is really a beneficent and often conquering ally against a more concealed opponent. In body and brain lies the center of our impulses and the controller of the weather in our souls.

Mind is to brain and body as the function of sight is to the eye. Who would try to discover the meaning of Sight with no reference to the eye, the retina and the optic tracts, or to the ability of the cortex to gather up and differentiate impulses to it and to unify or reject them? We should, thus, know nothing of sight: lacking such consideration we would know esthetics, visual esthetics, and we would be dwelling in this too as among the Mysteries. After all, in encephalitis there came morbid behavior and morbid emotional states emerging from lesions as organic as a fractured femur and we must believe that such cases furnish precious knowledge of neurotic and psychotic happenings from a physical rather than from emotional or psychic causes.

All the specific fevers have their nervous concomitants. Is it not strange in us that a patient with pneumonia, who, harassed by delusions of imminent destruction, throws himself from a window, is classified as delirious from fever, while a similar psychic situation with no obvious intoxication may be called cyclothemia, the organic pathology of which most psychiatrists deny? One patient is said to have a disease of the body, the other a disease of the mind. This is at once loose and dogmatic thinking. Only in Wonderland can we find the grin without the cat. We must educe a pathology for neuroses and psychoses—and they are only two parts of the same spectrum—through medicine; the effort to do so through philosophy and psychology has not succeeded. These are useful till our knowledge of the body will have grown to a larger stature. In therapeutics they deal well enough at times with symptoms, but a sharper sword must today be forged by medicine to deal with the nature of mental illness itself.

Often one hears a proper plea from the psychologist for a consideration of the human animal as a whole. One can understand his meaning in that the metazoic multicellular animal functions in each act, as uniquely, in as unified a manner, as does the unicellular animal. Each act of behavior is the resultant of the forces in the organism, so that, I think, one may properly speak of the human being as acting as a whole, which, of course, is not the same as feeling or thinking as a whole.

Many have described Freud's philosophy, Freud's theories, as being a purely motivistic relation of human behavior. One feels, however, not that Freud's point of view is incorrect but that it is true only in part. It is only one angle of view. Our mind symbolizes everything we see; we see but one aspect at a time, and that, first and clearest, which appeals to the consciousness of the observer. The important thing is to try to have more than one line of attack and more than one angle of vision; but the psychoanalyst seems to see like Polyphemus with but a single eye, and one cannot but feel that there is a certain belief in his circles that they have absorbed psychiatry, that, without their rigid technic and ritual, one is not a psychiatrist, and that he

who is not for them is against them. This is on the banner of all religions but is on the banner of no science.

Fanatics have their dreams, wherein they weave  
A paradise for a sect.

It is suggested that one has no power to appraise human personality in other terms than theirs. Now Shakespeare was not a psychoanalyst, nor Voltaire, nor George Meredith, nor Thomas Hardy, but I venture to say that these men knew more of the human spirit and the motivistic phenomena that prevail in the human heart than most of Freud's disciples. The great artists, so far, have been perhaps the greatest of all psychiatrists. Their understanding may be better than our knowledge.

So, I feel the freudian contribution to be this: Freud has demonstrated that there is a phylogeny of personality. We have long known that physically each of us is a developmental microcosm of our race. From the egg to maturity we pass through stages in our body at least similar to those through which the whole race has passed. Freud, however, has made it clear that in our emotions, in our strivings, in the preponderance of this instinct over that at different periods of our lives, we have a like phylogenetic evolution—and, if we live long enough, devolution—of instinctive growth and personality; that the child is a polytheistic savage, that its sexual instincts emerge by gradual progression from a preoccupation with one orifice of its body to a preoccupation with another. Freud himself, however, has said in his last lectures that he is not sure it is a contribution to therapeutics. And, indeed, few men feel better or happier when reduced to their lowest common denominator—and some despair and are degraded when confronted by the kitchen-rebellion of their antique urges.

Nevertheless, this work does make it clear how our instincts have developed within the microcosm of each man's body. However, we have physical vestigial remnants like gill-slits, and instinctive and emotional vestigial remnants like sexual reversions and scatologic tropisms; but we'd be foolish to appraise the total body in terms of the one or the total personality in terms of the other.

Further, the assurance with which symbolistic theories are applied tends to give our thoughts and orientation away from ideas which promise much from other points of view. The work on the metabolism of brain tissue, on the chemistry of the nerve-impulse, on the rôle played by vitamins and enzymes in neural nutrition, on mood changes associated with blood sugar variation, on the significance of the temporary appearance of menopausal vaginal epithelium in young women passing through cyclic mental depressions—these notions are just appearing over our horizons. If we should tend to limit our enquiries into neurotic and psychotic behavior to any pontifical doctrine, be content with patterning and docketing of mental phenomena, with the formalism and rigidity and humorlessness of the chemical analytic tables of our student days, then I say we are deserting the spirit of medicine for Alexandrine scholasticism. We are asked to regard each human being as a single unswerving, unchanging uniformity against which environmental stimuli are directed. Should we postulate that each individual invariably reacts to these in the same way as does every other individual, and according to "the book of words,"

then we are saying something, contrary, I am sure, to human experience and to common sense.

Individuals differ as much in their personalities and reactions as in their faces. They differ, as even Freud has admitted, in their inherited endowments. Nor is inherited endowment a fixed concept. There is certainly such a thing as the inheritance of acquired characteristics. Our trouble is that we see this problem narrow and we see it short. We think in far too small units of time. We cannot see the results of inheritance of acquired characteristics because of the paltry shortness of our own lives; and, because our eyes are holden, our minds are holden also.

There is much evidence in the animal world that such transmission of acquired characteristics exists, that a defective germinal cell will produce a defective descendant and that the defective descendant will procreate a defect in his descendant. If that can happen in the lower animals it can happen to us; only our nervous systems are so complex, they are so much more evolved, that we cannot see these changes in them in terms of our little lifetimes.

All of this is far from denying the reciprocal influence of emotional stress on bodily tissue. Strain and unhappiness produce gastric ulcer. In both civil and military life, we've all seen fright produce hyperadrenalism and acute enlargement of the thyroid. Many allergic persons react to their specific protein only when their autonomic systems are, as it were, "triggered" by emotion. This shadow country where the saints dwell and where soma and psyche are wedded is perhaps the Never-Never Land of Medicine. If we should learn it enough for geography and charts, we may learn to control personality and thereby lose our humanity. However, war and the stupidity of statesmen may be depended on to destroy civilization before disaster comes to us through too much knowledge.

Of course, the pressure of sex, the pressure of hunger, the pressure of the herd, impinge on and mold, modify and direct the growing organism. A potential homosexual may be made a complete homosexual by education and experience, but I believe he must be biologically nearly a complete homosexual not to resist the normal trend of physiologic living.

If environmental stresses are the causes—as indeed most laymen believe—of mental breakdown, there would have been an epidemic of dementia praecox and manic-depressive insanity during the war, and during the depression. However, all this is far from advocating a mechanistic approach to the study of functional or "reversible" disorder. But one pleads that we employ all our physiologic knowledge as well as our knowledge of anthropology and psychology to find out the nature of the mind of man, and not limit our approach to any one arbitrary symbolistic theory. We should treat man as a dynamic and a physiologic whole.

Our attitude is more a biopsychic approach than a mechanistic approach and is an effort not to be satisfied to explain the unknown by something equally unknown. We must believe that we cannot have intellect or ecstasy without a good neuron endowment. The strategic outlines and boundaries of mind are laid down by physical heredity; its tactical plan by social inheritance, by education and by the molding pressures of sex, the herd and hunger. All may be destroyed by infection or degeneration.

As yet we can throw no light on the intrinsic nature of mind and are forced mainly to apply with some

empiricism psychologic remedies to psychologic ills. We are now only picking at the locks of doors behind which lie the answer to these mysteries. Many keys will be needed for the opening, but it surely will not be beyond man's wit to make them.

410 East Fifty-Seventh Street.

## THE CLINICAL USE OF DIURETICS

JOSEPH M. HAYMAN JR., M.D.

CLEVELAND

Diuretics are drugs used to increase the volume of urine. This presupposes the kidneys to be in such condition that the formation of urine is possible; there must be at least a certain degree of parenchymal integrity, a sufficient blood pressure and an adequate blood flow. These facts are not infrequently overlooked, and attempts are made to increase the flow of urine by diuretics when they are bound to fail. For instance, in the oliguria or anuria of surgical shock and Addison's disease, efforts to raise the blood pressure will have much more effect on urine excretion than will diuretics. In the oliguria of congestive heart failure diuretics are much more effective when the circulation has been improved by rest or by rest and digitalis. In the anuria of mercury bichloride poisoning, no diuretic will increase the excretion of urine until a certain amount of regeneration has taken place in the tubular epithelium.

Presumably, as emphasized by Peters,<sup>1</sup> diuretics do not cause either a chemical or a biologic revolution in the body but work through existing physiologic mechanisms. The formation of urine is complex, but recent work has brought a reasonable amount of agreement on the processes involved. The first is separation in the glomerulus of a normally protein free ultrafiltrate of plasma, containing all the soluble substances present in plasma, and in the same concentration. As this ultrafiltrate passes down the tubule it is concentrated by the reabsorption of water by the tubule cells and modified by the reabsorption of dextrose, sodium chloride and certain other salts and by the secretion of some dyes, such as phenolsulfonphthalein, and a certain amount of some other substances. Hence a diuretic must in general act in one of two ways. It may increase the volume of glomerular filtrate or decrease the reabsorption of water in the tubule.

A certain decreased reabsorption of water probably results from any increase in the volume of glomerular filtrate but is much more effectively produced by a high concentration of certain salts in the filtrate or by drugs, such as mercury, which inhibit the reabsorptive power of the tubular epithelium. There is little to support the conception that the chief action of any diuretic is change in the "water binding" power of the serum proteins, in spite of much discussion of the subject, especially in the German literature.<sup>2</sup>

From the Department of Medicine, Western Reserve University School of Medicine, and the Lakeside Hospital.

Read before the joint meeting of the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

H.: *Ueber die Auslösung intermediärer Kochsalzverschiebungen von Zentralnervensystem aus*, Arch. f. exper. Path. u. Pharmacol. 65:189 (Aug.) 1920.

While there are conflicting opinions in the literature concerning the mode of action of many diuretics, there is good evidence, I think, that examples can be found among those commonly used of each of the actions mentioned.<sup>3</sup>

The caffeine or rather xanthine group, shown long ago by von Schroeder<sup>4</sup> and more recently by Richards and Plant<sup>5</sup> and others to exert their action directly on the kidneys, must either increase the volume of glomerular filtrate by an increase in glomerular capillary pressure due to local vascular adjustments within the kidney or decrease tubular reabsorption. The latter was rendered unlikely by the experiments of Filehne and Biberfeld,<sup>6</sup> while the former is consistent with the work of Richards and his associates.<sup>7</sup>

Digitalis was introduced into therapeutics by Withering as a diuretic, and squill, which resembles it in action, has been used for this purpose for centuries. The consensus based on many experiments is that the diuresis from these glucosides is not due to any direct effect on the kidney but is the result of their action on the heart and circulation, with the consequent improvement in the blood flow through the kidney. They produce little or no diuresis in a normal man. These groups, then, may be thought to cause diuresis by increasing the volume of glomerular filtrate.

The diuresis produced by water, urea, sugars, neutral salts such as potassium chloride, or sodium sulfate and the "acidifying" salts such as ammonium chloride and calcium chloride is probably in part due to a temporary hydremia with dilution of plasma proteins and in part to the presence of these substances in high concentration in the glomerular filtrate interfering with tubular reabsorption. Diuresis due to diminished tubular reabsorption is best shown, however, in the action of mercurials—mild mercurous chloride and its newer substitutes merbaphen, salyrgan or mercupurin,<sup>8</sup> and substances such as chromates and uranium used experimentally but not clinically.

The diuretic action of mild mercurous chloride was apparently first recognized by Jendrassik<sup>9</sup> in 1886 and was studied experimentally by Streyer.<sup>10</sup> But the effect was uncertain and other actions were undesirable. With the introduction of merbaphen by Saxl and Heilig<sup>11</sup> in 1920 the use of mercurial diuretics has increased rapidly.

There has been much discussion of the mode of action of these mercurial diuretics, many German and a few American investigators believing the diuresis to be the result of extrarenal factors, such as change in the composition of the blood or in the water binding power of the plasma proteins. More careful and critical work, however, has shown that the diuresis is due to local

action on the kidney<sup>12</sup> and is best attributable to a decrease in the reabsorption of water in the tubules.

The continued use of merbaphen, however, was soon found to cause toxic manifestations in patients—salivation, gingivitis, colitis and proctitis. Attempts to alter the nature of the compound combined with mercury in an effort to decrease this toxicity led to the introduction of salyrgan by Brunn<sup>13</sup> in 1924. This compound was found to be at least as effective as merbaphen and less toxic<sup>14</sup> and has properly largely supplanted it. It can be given repeatedly, at intervals of a few days or a week, with continued effect and without apparent harm for a period of years.<sup>15</sup> Its disadvantages are that it is ineffective orally, that it is prone to produce venous thrombosis, and that intramuscular injections are painful. The last two can be overcome somewhat by washing out the vein with a few cubic centimeters of salt solution after the injection and by adding a local anesthetic. Recently, following the work of von Issekutz and von Vegh,<sup>16</sup> a mercurial compound which contains a cyclopentane in place of a benzene ring was introduced as novurit, known in this country as mercupurin. This contains 5 per cent theophylline, 3.5 per cent of which is stated to be in organic combination. Theoretically, the combined action of a xanthine which increases filtration and a mercurial which diminishes reabsorption should enhance the diuresis. This undoubtedly occurs in rabbits. Crawford and McDaniel<sup>17</sup> and DeGraff, Nadler and Betteman<sup>18</sup> and Herrmann believe it to be true in man as well, while Fulton and Bryan<sup>19</sup> found that, while mercupurin was an efficient diuretic, no preference could be given it over salyrgan. In my own comparison of these drugs, I chose to use them alternately in the same patients. All the patients suffered from congestive heart failure, had received full doses of digitalis and were on maintenance amounts when the drugs were given. The dose of each was 2 cc. intravenously. Salyrgan failed to produce a diuresis in three of twenty-one instances, mercupurin in three of nineteen. The average fluid intake on salyrgan days was 1,281 cc. and on mercupurin days 1,232 cc., and the average urine volume with salyrgan was 2,244 cc. and with mercupurin 2,766 cc. The difference in the mean urine volumes, 522 cc., is not statistically significant. Yet it must be said in favor of mercupurin that a net diuresis of 2,000 cc. or more resulted from its use more frequently than from salyrgan.

The use of an inorganic "acid producing" salt with a mercurial for the purpose of augmenting the diuresis was first reported by Keith, Barrier and Whelan.<sup>20</sup> In recent years the enhancing effect of such "acid pro-

ducing salts" has been repeatedly confirmed. Explanations, however, of the mechanism by which these salts affect the diuretic action are still at variance. Keith and Whelan<sup>21</sup> suggested that an abnormal acid reaction in the tissues was responsible. Others<sup>22</sup> believe that only those salts which caused a fall in the alkali reserve of the blood augment the diuresis, but their results have not always been consistent.

In a series of very careful experiments on dogs, Ethridge, Myers and Fulton<sup>23</sup> found that salyrgan diuresis was enhanced by acidifying salts (ammonium

degree of acidosis was greater on the second or third day of administration than subsequently, even when the drug was taken continuously. These salts should therefore be given intermittently. Such a program of salt for two days before and on the day the mercurial is given has been used by Saxl and Erlsbacher.<sup>26</sup> In many of the cases in our series these salts were without effect because given in inadequate doses, larger amounts not being tolerated. We have been unable to detect results from less than 6 to 10 Gm. of ammonium chloride daily. If a patient cannot take these quantities, there seems no gain in annoying him with smaller doses. While the salts alone will give a diuresis when given in adequate amounts, in my experience this is uniformly less than that produced by the mercurials alone or mercurials with the salts, and the uncertain result is outweighed by the disadvantages.

Now the most advantageous diuretic to use will depend on the condition of the kidneys and which of the foregoing processes, filtration or reabsorption, can be varied to the greatest degree.

The records of 213 patients with edema who were admitted to the Lakeside Hospital during the past eight years were studied in an effort to assay the value of diuretics. These patients were treated in the wards of a general hospital by a number of men. This has given us the opportunity to compare the results of the routine use of certain drugs with what may be accomplished by the same remedies under the more rigid conditions of special study. Those drugs which most regularly produce an effect, with the least discomfort to the patient and the least attention to special details, are the most valuable. The cases that have been reviewed were divided as shown in table 1. Table 2 shows the relative effectiveness of the more common diuretics in the different groups. An increase of 500 cc. or more in urine volume above the control level has been regarded as a diuresis. The degree of diuresis

Chart 1.—The diuretic effect of digitalis in congestive heart failure.

chloride, calcium chloride, ammonium nitrate, calcium nitrate) which caused a fall in plasma carbon dioxide. Three alkalinizing salts (potassium acetate, potassium bicarbonate, sodium bicarbonate) increased the plasma carbon dioxide and very definitely decreased the salyrgan diuresis. Sodium and potassium chloride had no appreciable effect. The differences in effect of these salts showed no apparent relation to changes in the level of whole blood chlorides. Blumgart<sup>24</sup> found that salyrgan diuresis was accompanied by a fall in plasma chlorides and a rise in carbon dioxide, which was prevented if an "acidifying" salt was given. It may be that the fall in chloride and rise in carbon dioxide following salyrgan acts in the nature of a brake on the diuresis and that the salts act by removing this brake. Often the diuresis from salt and salyrgan is a true synergism, the result being much greater than the sum of the two alone.

There are certain factors, however, that make the routine use of acidifying salts of less value clinically than might be supposed. They are all irritant to the stomach and if they produce vomiting not only disturb the patient but may lead to a relative alkalosis, which is known to diminish diuresis. If they are to be used at all they must be given in large doses, from 6 to 10 Gm. daily, for if they do not give a fall in plasma carbon dioxide they are of no value. They should be administered so as to afford their maximal acidifying effect during the time of action of the mercurial. The work of Dennig, Dill and Talbott<sup>25</sup> showed that the

Chart 2.—Increase in urine volume after paracentesis, as the result of the decrease in pressure on renal veins. Both patients had congestive heart failure and had received full doses of digitalis.

varied greatly. In many cases of congestive heart failure, digitalis in full doses led to as marked a diuresis as any other drug. When effective, the mercurials and urea usually produced larger urine volumes than the caffeine group, salts or sugars.

In the edema of acute nephritis, the major element is a general increase in capillary permeability throughout the body. At the same time, the capillary endothelium of the glomerular tufts is swollen, so that blood flow through the kidney is diminished. This can be

inferred from histologic sections<sup>27</sup> and is supported by perfusion experiments.<sup>28</sup> Here, as pointed out years ago by Christian,<sup>29</sup> diuretics have little place. They cannot be effective until the endothelial swelling has diminished, and they may do harm. All our patients with acute nephritis, with edema graded from 1 to 3 plus, were placed on a low salt diet with restricted fluids. In ten of the sixteen no diuretics were used. In the other six, xanthine derivatives, "acid" producing salts and hypertonic dextrose were exhibited with uniform failure. If increase in water intake, the blandest diuretic, is not followed by an increased volume of urine, no more powerful drug is likely to be effective.

In subacute or chronic glomerulonephritis with edema, unless of the "nephrotic" type, diuretics are again of little value. Digitalis should be given if there is any evidence of myocardial insufficiency. When it does produce a diuresis, it may be assumed that the edema is at least in part cardiac. There is no basis for the fear that digitalis may increase the hypertension. Feil and Steuer<sup>30</sup> have shown that the dosage is not affected by renal insufficiency. In the presence of impaired concentrating power of the kidneys, the mercurials are not only ineffective but are dangerous because of the likelihood of retention and mercurialism. Occasionally one of the xanthines will give a satisfactory diuresis. Keith and Binger<sup>31</sup> have reported favorable results from potassium nitrate in doses of 12 Gm. daily. In my experience the diuresis has not been marked. If diuresis is not produced in a few days, potassium salts should not be continued because of the danger of toxicity from marked accumulation of potassium in the plasma.

It is in congestive heart failure that diuretics have their greatest field of usefulness. But even here

with 1 or 2 plus edema, simple rest in bed led to a prompt diuresis and loss of all edema. In twenty-nine others, digitalis alone was all that was necessary. It gave a definite diuresis in 85 per cent of the cases in which it was used. The importance of mechanical interference with the circulation by ascites or hydrothorax must not be overlooked.<sup>32</sup> Frequently an abdominal paracentesis, and occasionally a thoracentesis, results in a marked improvement in excretion of urine.

All diuretics will be more effective after mechanical removal of any large accumulations of fluid. After maximum improvement by rest and digitalis, with reasonably sound kidneys and adequate blood flow, diuretics that diminish reabsorption are usually most effective, notably the mercurials. They provoke the greatest diuresis and with the most regularity.

Chart 3.—The diuresis from mercurials in congestive heart failure: S, salyrgan 2 cc. intravenously; M, mercupurin 2 cc. intravenously.

The xanthines usually produce some diuresis in congestive heart failure but of lesser degree than the mercurials. They have the advantage of being as effective by mouth as intravenously. They must, however, be given intermittently, for if administration is continued an initial diuresis quickly falls to the control level. By omitting the drug for a few days, or even a day, another diuresis can be produced. Theophylline is usually the most effective, theobromine next and caffeine least. The degree of gastric irritation is in the reverse order. Is there any evidence that aminophylline or theocalcin are better than theophylline? They apparently are less likely to upset the stomach.

Urea is another extremely useful diuretic, when there is no elevation of blood urea nitrogen, which has not come into common use.<sup>33</sup> It is readily soluble in water and if administered after a meal is unlikely to cause nausea. We have used doses of from 15 to 60 Gm. daily for from three to five days. The drug is then omitted for a few days and the course repeated if necessary. It gave a good diuresis in 83 per cent of the cases in which it was used. We have observed no toxic symptoms from its use, perhaps because it has been given intermittently, and because we have not used it in any cases in which the blood urea nitrogen was above 20 mg. per hundred cubic centimeters. Crawford and McIntosh<sup>34</sup> found that, with continued administration loss of appetite, nausea and vomiting occurred when the blood nitrogen rose to 70 mg. per hundred cubic centimeters. If it is kept below 45 mg., symptoms do not seem to occur.

Other diuretics, such as potassium salts, parathyroid and thyroid extracts, intravenous succrose, and a cottage cheese diet have occasionally been used. But our data are too meager to discuss.

In the edema accompanying the "nephrotic syndrome" and associated with massive albuminuria, low plasma proteins, normal blood nitrogen and high cholesterol, the prolonged use of diuretics is usually attempted. All will produce some diuresis at times. In the belief that the disease was metabolic, Epstein<sup>35</sup> proposed the use of thyroid extract and reported favorable results. While the basal metabolic rate was below normal in the majority of our patients, in only nine was it below —15 per cent. Thyroid extract, even in large doses, was effective in only 25 per cent of our cases. Caffeine derivatives are either ineffective or give only a slight transient diuresis. Potassium salts in some cases give a marked increase in urine volume. We have had more uniform success, however, with ammonium chloride and salyrgan, and with urea. When the urine is of high specific gravity, indicating a normal reabsorptive power of the tubules, in spite of their abnormal histologic appearance, albuminuria is not a contraindication to the use of mercury. If a diuresis is not produced, however, it should be used with extreme caution, for there is always a potential danger, which is indicated in the uniform increase in the number of urinary casts excreted after its use.<sup>36</sup> Urea, on the other hand, has been equally effective and we have observed no toxic effects. The mechanism of its action is not clear. It is a vasodilator and so may increase glomerular capillary pressure. It is not actively absorbed by the tubular epithelium and so may interfere with the reabsorption of water in the tubules.<sup>37</sup>

In portal cirrhosis, diuretics are commonly given in the hope of preventing the necessity of tapping, or at least of diminishing its frequency. Their value, however, is questionable. The older clinicians believed in early tapping and that diuretics were a waste of time. With the introduction of the mercurials, a new impetus

Chart 4.—The caffeine group must be given intermittently, for the diuresis fails after two or three days, even if the drug is continued.

has been given to their use. Favorable results have been reported from the Mayo Clinic<sup>38</sup> in a large group of cases. Fulton,<sup>39</sup> on the other hand, reported thirty-seven cases from the Peter Bent Brigham Hospital

presenting cirrhosis and ascites in which mercurials alone were found to be quite inadequate for relief of the ascites.

Our experience is in accord with this. In only one patient with ascites, and that of moderate amount, was sufficient diuresis obtained to make tapping unnecessary. In our experience the mercurials and urea are the only diuretics that produce sufficient diuresis and with enough regularity to justify their use, and of the two

Chart 5.—Diuretic effect of urea in "nephrotic syndrome."

the mercurials are the more effective. While it is difficult to prove, since the necessity for paracentesis varies with the progress of the disease, I have the distinct impression that the regular use of mercurial diuretics has prolonged the intervals between tapings in ambulant patients.

#### SUMMARY

Diuretic drugs should be regarded only as adjuvants to other methods of treatment in the removal of edema. There must be an adequate renal blood flow and a certain degree of parenchymal integrity in the kidney for them to be effective. They have no value in acute nephritis and rarely in chronic glomerular nephritis. Diuretics have their greatest usefulness in congestive heart failure, after the patient has been digitalized. Here the mercurials salyrgan and mercupurin are the most regularly effective. In portal cirrhosis with ascites, while diuretics have not prevented the necessity of tapping, the regular use of these mercurials has in my experience lessened its frequency. Patients with "nephrotic" edema have responded more regularly to ammonium chloride and salyrgan or to urea than to any other diuretics.

**A Pint of Beer and an Ounce of Fat.**—Physical exercise was obviously intended by Nature to be the chief means of countering a surplus food intake. Suppose that the sedentary worker's expenditure of energy is about 2,370 calories per day. If he spends his leisure time in walking, he will need an additional 57 calories per mile; half a pint of mild ale will provide him with that amount of energy twice over. If he does not expend it, it will be transformed into fat. Theoretically, one ounce of human fat can be formed in the body from an average pint of beer, probably not directly but by "sparing" other fuel foodstuffs. The beer drinker who has a predisposition to obesity must reduce his consumption of other carbohydrate foods, e. g., bread, if he wishes to keep his figure normal, or else take exercise in proportion to the total calory value of his day's rations. The obese patient living on a reducing diet need not give up his glass of beer, provided that its calory value is calculated into his dietary scheme.—Christie, W. ## THE VALUE OF FEVER THERAPY FOR GONORRHEA

C. A. OWENS, M.D.

OMAHA

My purpose in this report is to present the results obtained by treating 100 patients having gonococcal infection by artificial fever. Physically produced fever in the management of gonorrhea is not to be regarded as just another treatment method to be added to the countless ones in which all physicians have been disappointed, for the results to be described can be and are being duplicated by others. It will not be claimed that gonorrhea is now any more curable than it formerly was, because the older methods, with sensible application and faithful cooperation on the part of the patient, generally resulted in cure; but great patience and perseverance was often necessary, and serious complications often occurred somewhere along the tedious course of the disease. Too frequently both patient and doctor became discouraged or careless before a cure was accomplished.

Fever therapy now offers immediate symptomatic relief and cure in such a great majority of cases that the patient may actually be promised such relief where formerly no prognosis whatever could be given.

### RATIONALE OF THE TREATMENT

Whether the gonococcus is killed in the tissues solely through the effect of temperature maintained for several hours in the neighborhood of 106.5 F. is not definitely proved. The clinical effect of such exhibitions of artificial fever on gonococcal disease furnishes weighty evidence in support of the assumption that this is true. Two previous articles by Desjardins, Stuhler and Popp<sup>1</sup> thoroughly review the literature relative to the cultural behavior of the gonococcus under various physical conditions. Careful bacteriologic studies by others<sup>2</sup> seem to show that 99 per cent of laboratory gonococci can be destroyed while growing in ideal surroundings by exposing them to temperatures of 41 C. (105.8 F.) for five hours. The thermal death time of organisms *in vitro* must logically be different from what it is *in vivo*, and until it becomes possible to recognize and measure the antigenic factors present in the host's tissues, one cannot know whether gonococci occurring as guests in the urethral glands are more or less resistant to heat than those growing in test tubes. Likewise nothing as yet is known concerning the effect of high temperatures on tissue resistance. The exact manner in which the beneficial influence of externally induced fever is exerted is no better understood than the influence of fever resulting from injections of foreign protein. These two types of artificially induced fever have marked differences, however, in that one is biochemical and toxic in its action while the other is physical. Moreover, the one is shocklike in its sudden appearance, rapid rise to a peak and just as rapid fall, whereas the other can be maintained constant at a high level until the desired time of exhibition has elapsed. It is the

accuracy of control for both degree and duration of temperature in the new method that has made possible the remarkable results.

### OBJECTIONS TO THE TREATMENT

After a fairly extensive and pleasant experience with a therapeutic method, one is liable to minimize specific objections that appear to others to be of alarming proportions. I will try to be unbiased. Although I think I know the effect of heat on the micro-organism, I do not know the exact effect of such continuous high temperature on all the vital processes of the patient. The observable reactions of the body to vigorous prolonged heating, such as changes in cardiac function and in blood pressure, can be described in detail, but one does not rest assured that these indicators tell the entire story of nature's response to this therapy. However, the fact that one does not understand all the influences at work in a useful therapeutic measure should not mitigate one's enthusiasm in its use unless it can be shown that the method is dangerous, and such danger has not been proved by any manifestations other than minor complications herein described. Aside from the actual discomfort to the patient, the use of temperatures

Fig. 1.—The Kettering hypertherm with patient in place.

reaching 107 F. is alarming to the doctor who feels that one more degree of elevation for even a few minutes would be almost certainly fatal. There is no real answer to this objectionable feature, and it weighs so heavily with medical men that it is now and probably will remain for some time the chief obstacle to the extensive use of the treatment. The danger of overheating makes necessary the utmost exactitude of design and control of the mechanical equipment and the most meticulous care on the part of specially trained attendants. Under these circumstances, the method can never be carelessly employed as a routine or office type of treatment. It is strictly a hospital procedure for selected cases. An answer to the overcautious among the profession is the fact that in this group of cases there have been no serious complications from overheating. The procedure does appear heroic to those unfamiliar with it, and the objection is sometimes offered that this is a form of therapy the severity of which is all out of proportion to the dangers of the disease being treated. I can do nothing but grant all this and say that no permanent ill effects of the treatment have been seen, and that the majority of intelligent patients voice no regret that they have had the experience.

From the Departments of Urology and Fever Therapy Research, University of Nebraska College of Medicine.

Read before the Section on Urology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

## EQUIPMENT

Since the work being done at the Clarkson Hospital in Omaha is part of a research project initiated by Dr. Walter M. Simpson of the Miami Valley Hospital in Dayton, Ohio, there is the same physical equipment and general conduct by personnel at this clinic as in the others taking part in the same project. The cabinet is the Kettering hypertherm,<sup>3</sup> which combines the features of simplicity of operation with dependability and absolute accuracy of control. It accomplishes the raising of the patient's temperature to the desired degree solely through the means of recirculated hot moist air. There are no electrodes in contact with the patient and no jacket or restraint of any kind is necessary. The patient lies entirely within the cabinet with only his head outside, but the attendant has ready access to the entire body surface through large sliding doors in each side of the cabinet, these making easy the constant attention to the skin and the frequent taking of rectal temperatures.

## CONTRAINDICATIONS

Aside from the debatable objections to this form of therapy, there are some definite contraindications and these are essentially the same as those for nonspecific protein therapy. In brief, they are advanced vascular and renal changes, cardiac weakness, chronic debilitating diseases, chronic alcoholism, and marked nervous and emotional instability. It is to be noted, however, that such conditions, with the exception of alcoholism, are not commonly associated in patients who contract gonococcal infections.

## THE PROCEDURE

After general examination of the patient has demonstrated no marked renal or vascular disability, he is instructed to drink excessive quantities of water and milk the day before he is to enter the cabinet. The morning of treatment he appears without breakfast and is placed in the previously warmed cabinet. Temperature and blood pressure readings are recorded, the extremities are encased in cotton blankets to protect the skin, which shows more tendency to react unfavorably here than on the torso, and the cabinet is closed with a sponge-rubber contact reinforced by a loose towel acting to stop the free space about the neck. A cold moist cloth covers the forehead, and the breeze from an electric fan is directed on the face. Pentobarbital sodium,  $1\frac{1}{2}$  grains (0.1 Gm.), is given as a sedative just before starting the treatment. Temperature rises with a rapidity varying slightly with the individual, and the average time required for it to reach  $41.4^{\circ}\text{C}$ . ( $106.5^{\circ}\text{F}$ .) is between sixty and ninety minutes. It is during this time of temperature rise that most patients experience some difficulty. How troublesome this period of apprehension or excitement becomes depends almost entirely on the mental caliber of the patient. If he is a forceful type, determined to secure the benefit he desires and able to exert self-discipline, he will go through it nicely. The average patient is very cooperative and, after the temperature reaches a stationary level, many go to sleep for long periods. Some will require sedatives to allay their restlessness and for this purpose a hypodermic injection of one-third grain (0.02 Gm.) of Pantopon is usually sufficient. As the treatment progresses the average patient perspires

freely, and since the loss of chlorides must be prevented, he is encouraged to take large quantities of cold physiologic solution of sodium chloride. There is generally no objection to the salt solution, but when there is distaste for it, other drinks such as plain water or carbonated beverages are used freely.

Frequent observations of the condition of the skin are made through doors of the cabinet. The position of the patient may be changed from the supine to the prone, and the wrappings protecting the extremities are frequently removed and replaced. Areas of excessive erythema may be painted with tincture of benzoin, rubbed with pieces of ice or bathed with liquid petrolatum. By constant attention to such details the attendants may prevent serious burns, but at temperatures ample for gonococcal therapy minor blisters or first degree burns are common enough so that the patient is always warned concerning them. One small second degree burn has occurred.

The temperature is not allowed to go above  $107^{\circ}\text{F}$ . If it appears that the temperature will exceed  $107.2^{\circ}$ , an immediate sponge bath is given, and if a patient is

Fig. 2.—Average systolic and diastolic pressure, with temperature and pulse rate, compiled from the records of thirty-six treatments given fourteen men between the ages of 22 and 42. A, systolic pressure; B, pulse beats; C, diastolic pressure; D, temperature.

found to tolerate treatment badly as indicated at any time by extremely rapid or erotic pulse, he is taken out immediately. A well tolerated initial treatment is no proof that the patient will have more or less tolerance in subsequent sessions with the exception that it is an indication of how the skin will tolerate the heat. There can be no relaxation of vigilance by attendants alert to note the least sign of trouble at any time during any session.

Nausea and vomiting during a treatment will occur if food has been taken against orders. Occasionally patients vomit in spite of fasting and require the use of from 500 to 1,000 cc. of 10 per cent dextrose in physiologic solution of sodium chloride intravenously to control it. When nausea occurs after the treatment, either immediately or the day following, gastric lavage will generally give relief. In a few, additional intravenous fluids have been necessary after leaving the cabinet.

After completion of the required number of hours, the sliding bed is pulled out of the cabinet and the patient, protected by blankets, is allowed to cool. Generally about one hour is required for the temperature to return to normal. He is then allowed to walk if

3. The recent progress in artificial fever therapy could not be possible without this cabinet, which represents an excellent engineering service rendered by the Research Laboratories of the Frigidaire Division of General Motors Corporation and made available through the courtesy of Mr. C. F. Kettering.

is analogous to surgical procedure or, in other words, that the patient must be a surgical risk before fever therapy can be prescribed safely. The great danger of publicizing the successful institutional treatment of gonorrhea with fever therapy lies in the fact that others will attempt to make it an office procedure. I have had a fever therapy apparatus in my office for two years. I believe I know its dangers and its limitations. I have not cured a case of gonorrhea with it nor have I killed any one. However, there have been tragedies in my own state due to this type of treatment. One physician who purchased an instrument similar to mine could not be here today to tell you how he killed a man with a temperature of only 105 F. while treating him for gonorrheal urethritis. One physician here today has intimated that, if the patient wishes to assume the responsibility, fever therapy may be given for gonococcal infections. With this I differ emphatically. A physician does not have the right to allow a patient to take this responsibility in most cases. For the treatment of certain complications, such as gonococcal arthritis and gonorrheal ophthalmia, fever therapy is a most necessary addition to our armamentarium. However, in alleviating these complications one does not necessarily have to give the extreme temperatures that have been mentioned here today. Another point that should be emphasized is that the thermal death point of the gonococcus is only one-half degree Fahrenheit below the average thermal death point of man. The difference in these thermal death points is too small to allow fever therapy to be used as a treatment for gonorrhea.

DR. O. A. NELSON, Seattle: Recently I listened to a review of the records of 300 patients treated by pyrexia at the Puget Sound Naval Hospital at Bremerton, Wash., where this work is under the direction of Lieutenant Commander Potter. He stated that his results are satisfactory in the acute gonococcal infection of the urethra, prostate, seminal vesicles or joints. He contended further that although the gonococcus was killed by these treatments in the chronic stages of posterior urethritis the pus organisms persisted, so that clinically the patients were not materially improved. Consequently I am rather astonished to hear Dr. Ormond say that he is getting satisfactory results in cases of chronic gonorrhea. At the Swedish Hospital, Seattle, about thirty patients have been treated by this method for gonorrhea. One death occurred at this institution. The patient was a woman, aged 32, who went into shock in her initial treatment when the temperature reached 105.5. Although treatment for shock, such as infusion of saline solution and dextrose and blood transfusion, was promptly instituted, she died within twenty-four hours after the onset of shock. I believe that the preparation of the patient is important and that the patient should be given a high carbohydrate diet before the treatment is begun, for it has been found that in some instances the blood sugar has been reduced by a single treatment from normal value to 48 mg. per hundred cubic centimeters of blood.

DR. HERMAN L. KRETSCHMER, Chicago: There are several points that Dr. Owens should emphasize when he closes the discussion; he should emphasize again the fact that this form of treatment is used only in carefully selected cases and in cases that are carefully supervised. It is not used when certain definite contraindications are presented. It might be well to call attention to the fact that the treatments are discontinued immediately when there is a drop in systolic blood pressure and when the pulse rate rises above 160. This is a new form of treatment and I believe it is well to emphasize its limitations, its contraindications and its dangers. The wave of enthusiasm for any mechanical device is always great. It is because of this wave of enthusiasm that it is well to call attention to the possible dangers with this form of treatment. In the few cases in which my associates and I have used it, the results were nothing short of spectacular and this has been the experience of others. I agree with most of the speakers to the effect that gonorrheal infection occurs in young people who are in the prime of life and who suffer from a disease that has practically no mortality; therefore it seems to me that a death from this form of treatment is a very high price for treatment.

DR. C. A. OWENS, Omaha: Dr. Kretschmer has already emphasized most of what I wished to add. Dr. Stuhler has called attention to a fact not previously mentioned and that is the increased effectiveness of local treatments carried out in the office following partial fever therapy. My experience has

been similar to his. My figures show 24 per cent of patients who refused to continue, but I have been agreeably surprised in most instances to find these cases clearing up much more rapidly with routine office treatment than they might have done if they had not had some artificial fever. I have been cautious about giving treatments of longer than six hours' duration, feeling that such prolonged heating might be unduly dangerous. I confess I am not the most enthusiastic member of the group at Omaha, but being the urologist I have been involved as an observer of results. I am enthusiastic, but not to the degree of being ready to submit all types of patients to this form of treatment. Dr. Warren stated that from 60 to 80 per cent of gonococcal infections will get well of their own accord. If that statement is taken seriously it will help account for the good results reported for many so-called remedies for gonorrhea and it will also help to restrain the tendency to use a rather heroic treatment too freely. Dr. Ormond mentioned the use of multiple treatments. I am beginning to feel that if a marked improvement does not occur after one or two full treatments of six hours each there is no justification for further treatments. I am so respectful of the severity of this procedure that I do not urge any one to continue unless definite evidence of improvement appears after two sessions of fever. The laboratory aspect is being ably cared for and we, as clinicians, should be interested enough to give a thorough and careful trial to any procedure appearing to merit such a trial. Certainly, fever therapy has demonstrated such a merit.

## THE PHENOMENON OF LOCAL TISSUE REACTIVITY TO BACTERIAL FILTRATES

THE RÔLE OF ALTERED VASCULAR RESPONSE  
IN CERTAIN HUMAN DISEASES

GREGORY SHWARTZMAN, M.D.  
PAUL KLEMPERER, M.D.  
AND  
ISADORE E. GERBER, M.D.  
NEW YORK

The phenomenon of local tissue reactivity deals with a new category of antigenic toxic principles from a great variety of pathogenic micro-organisms. Their physico-chemical and immunologic properties are similar to those of true exotoxins. These principles are soluble and filtrable and may partially lose their potency or disappear altogether from the once highly potent filtrate. They are not dialyzable and are inactivated by ultraviolet radiation. The most important feature is that the principles are antigenic and neutralizable by specific immune serum according to the law of multiple proportions. The important distinction between the toxic principles of the phenomenon and true exotoxins lies in the mechanism of their effect. True toxins produce direct injury following a single injection. The active principles of the phenomenon elicit a state of tissue reactivity. If the principles are introduced into the blood stream during the time of reactivity they produce severe damage in this tissue.

The tissue damage manifests itself as a severe hemorrhagic lesion in which vascular injury is the outstanding feature. Studies of the prepared skin site at various intervals following the intravenous injection of the reacting factors indicate that the tissue changes present themselves in the following order: There first

ensues a marked degree of venous and capillary dilatation and engorgement. This is immediately followed by severe hemorrhage, which probably results from diapedesis since but few ruptured capillaries are evident. Shortly thereafter there occurs a striking degree of edema and an intense leukocytic infiltration. At this time many of the veins and capillaries are seen to be filled by thrombi, and in rare instances the arteries may be similarly involved. The thrombi consist of amorphous, granular masses, probably platelets, with enmeshed leukocytes and erythrocytes; fibrin strands are often demonstrable. The lumens of the venules and capillaries are completely filled by the thrombi; in the larger vessels they are seen as parietal clumps. Significant endothelial alterations are not seen either at the site of the thrombi or elsewhere in the vessels. Frequently there is a marked perivascular leukocytic

however, that the inflammation which may occur with skin preparation is independent of the skin preparatory potency of the filtrate employed and hence is no index of the state of tissue preparedness for the phenomenon. When the skin site is prepared with filtrates of high potency there is but slight inflammation, and in such instances there is no evidence of vascular injury. It seems, therefore, that there may be no morphologic evidence for the state of preparedness of the tissues.

The state of reactivity, therefore, with which one deals in the phenomenon is not comparable to any condition hitherto described and represents some functional disturbance in the susceptibility of the tissue. A large number of various nonbacterial substances tested failed to elicit the state of reactivity. The differences between this phenomenon and local anaphylaxis and bacterial hypersensitiveness, strongly emphasized in previous publications,<sup>1</sup> do not belong to the scope of this paper.

While the state of reactivity can be elicited exclusively by certain bacterial principles, potent provocative factors may be obtained not only from bacteria but from nonbacterial preparations as well. Thus, intravascular combinations of animal proteins with passively or actively acquired homologous antibodies invariably induce severe hemorrhagic necrosis in tissues previously made reactive through preparation with potent bacterial filtrates.<sup>2</sup>

It is essential that the provocative injection be given into the blood stream. The preparatory effect, however, may be elicited in one of the three following ways:

1. Preparatory injection of active bacterial filtrate into the skin or parenchyma of internal organs (local perivascular preparation); dermis, lung (Shwartzman<sup>3</sup>); liposarcoma of guinea-pig (Gratia and Linz<sup>4</sup>); stomach (Karsner, Ecker and Jackson<sup>5</sup>); knee joint (Moritz and Morley<sup>6</sup>); appendix (Latteri<sup>7</sup>); kidney (Loi and Cardia<sup>8</sup>); adrenal (Gronchi<sup>9</sup>); conjunctiva (Cassuto<sup>10</sup>); pancreas (Reitano and Loi<sup>11</sup>), and so on.

The optimum interval of time between the preparatory and the provocative injection is twenty-four hours, although in some rabbits an interval as short as eight

Fig. 1.—A, typical reaction; B, petechial hemorrhages following application of suction to a normal portion of skin distant from the site of typical reaction at A.

infiltration, and in some instances infiltration and edema of the vessel wall occur. The affected skin site subsequently presents a large central area of necrosis. Vessels at the periphery of the necrotic site may show organization of the thrombi. The final course of the injury is that of repair by granulation tissue growth and fibrosis.

Histologic sections of the prepared skin site in instances in which a provocative injection is not administered may show varying degrees of inflammation, which are dependent on a number of nonspecific factors. These may include the diluent employed in the preparation of the "agar washings" filtrate and substances probably resulting from bacterial autolysis. Further, the inflammation may vary with the type of organism used. The only vascular alteration that may be seen in such instances is the presence of perivascular collars of leukocytes with occasional infiltration of the vessel wall. Significant endothelial alterations or thrombi are not seen. It can readily be demonstrated,

hours may be sufficient. The duration of reactivity induced depends on the potency and dose of the bacterial preparation and ordinarily disappears within forty-eight to ninety-six hours.

2. Injection into the vascular system of an organ (local vascular preparation). In 1929 the following experiment was performed (Shwartzman<sup>3</sup> and Baehr): Kidneys in rabbits were exposed by median laparotomy.

Fig. 2.—Histologic appearance of petechial hemorrhages at B (Fig. 1) Subepidermal capillary hemorrhage. Thrombosis absent.

The left renal vein was clamped off and 0.5 cc. of *Bacillus typhosus* "agar washings" filtrate was injected into the left renal artery. The clamp was released five minutes following the injection. The right kidney received an injection of phenolized saline solution under the same conditions. Twenty-four hours later *B. typhosus* "agar washings" filtrate, in a dose of 100 reacting units per kilogram of body weight, was injected into the ear vein. Twenty-four hours after the provocative injection the left kidneys showed severe hemorrhagic and necrotic lesions of the cortex and medulla. No gross lesions were observed in the right kidney. Systematic histologic studies were not made at the time. It was concluded from this experiment that the preparatory factors are capable of eliciting a state of reactivity by way of the vascular system of the kidney.

Since the vascular system of the kidney possesses an unusually high degree of permeability, which may be altogether different from other organs, it was of interest to determine whether a similar mode of preparation could be successfully obtained in the rabbit's ear. It was found that the state of reactivity could not be elicited by a preparatory intravenous injection of bacterial filtrates alone into clamped and nonclamped ears. The state also failed to appear in combination

with cold, xylene, ethyl urethane, pilocarpine hydrochloride, atropine, calcium gluconate, guinea-pig liver extract, histamine dihydrochloride, epinephrine chloride and solution of posterior pituitary.

Preparatory intravenous injections of active principles, however, were capable of eliciting the state of reactivity in the rabbit's ear when they were accompanied by thermal hyperemia; i. e., exposure to 45, 50 and 55 C. It was also possible to induce the state of reactivity when a mixture of the preparatory factors with testicular extract was given into the veins of clamped ears. The incubation period required may be less than two hours.<sup>12</sup>

As may be concluded from the macroscopic and microscopic studies on the phenomenon, in all probability the state of reactivity takes place in the elements of the terminal vascular bed of the tissue prepared, after a suitable incubation period. Under ordinary conditions of intravascular preparation the contact of the preparatory factors with the vascular wall lasts only as long as the circulation is stopped and probably ceases when it is reestablished. If, however, a state of enhanced permeability is induced by means of testicular extract (Reynals' factors), a diffusion of the bacterial factors is allowed from the vascular channels into the perivascular tissue. A perivascular depot of active principles

Fig. 3.—Section taken of an area 3 cm. away from the site of a typical reaction of the phenomenon in the rabbit ear and showing in the gross cyanosis and edema. Thrombi in the venules. Reproduced from the *Journal of Experimental Medicine* 62: 621 (Nov.) 1935.

thus created may, then, induce the state of reactivity through contact with the local vascular network after the necessary length of time.

The natural high permeability of the kidney vascular supply may allow the perivascular deposition of pre-

12. Shwartzman, Gregory: The Phenomenon of Local Skin Reactivity to Bacterial Filtrates: Elicitation of Local Reactivity by Way of the Vascular System, *J. Exper. Med.* 62: 621-644 (Nov.) 1935.

paratory factors from the circulating blood, making it possible to elicit the state of reactivity by way of the local vascular system without the use of additional agents.

3. Preparation of organs by a preparatory injection of the bacterial filtrate into the general circulation.

Gratia and Linz<sup>13</sup> injected two doses of bacterial filtrate intravenously twenty-four hours apart and

Fig. 4.—Horse immunized for a period of two years by weekly subcutaneous and intravenous injections of meningococcus filtrates and vaccines. Glomerulus with capillary thrombi.

observed hemorrhages in the internal organs in guinea-pigs and rabbits. Subsequently, Apitz<sup>14</sup> found that a single dose of filtrate, when given intravenously, produced similar changes in the lungs, liver and spleen but that lesions characteristic of the phenomenon were obtained in the kidneys only when the animals received two doses, twenty-four hours apart.

A similar series of experiments with measured doses of bacterial filtrate confirmed Apitz's observations.<sup>15</sup> It was found that a single injection, even though greater than the sum of two injections given twenty-four hours apart, always failed to produce a renal lesion. The necessary interval between the two injections was twenty-four hours. When the interval was decreased to six hours or increased to forty-eight hours, no lesion was obtained. However, when testicular extract was given simultaneously with the first dose it was found possible to obtain the phenomenon in the kidneys with an interval of from one to five hours between injections.<sup>16</sup> No doubt the same mechanism, namely, enhanced vascular permeability, was operative both in this and in the ear experiments.

Histologically, the renal alterations occurred in the form of focal or diffuse symmetrical cortical necrosis with arterial necrosis and thrombosis, focal glomerular capillary thrombosis and necrosis of adjacent tubules, interstitial hemorrhage and isolated focal tubular necrosis. The thrombi were similar in structure to those observed in the skin lesions. A single injection was without any effect on the kidneys.

It is thus evident that the phenomenon may also be obtained by preparing the tissue by way of the general

circulation. Thus far it has been possible to prepare only the kidney. As previously indicated, this might be accounted for by the naturally high degree of permeability of this organ.

Regardless of the method of preparation, the striking macroscopic alteration is the hemorrhagic character of the tissue response, and microscopically this is expressed in severe vascular damage; i. e., hemorrhage and thrombosis.

Evidence indicating that the lesions of the phenomenon are associated with manifestations of altered vascular response is demonstrated by the following experiments:

An area of skin prepared by the injection of bacterial filtrate responds in a normal manner to various stimuli, such as mechanical irritation, application of heat (from 50 to 70 C.), massage, epinephrine, histamine, calcium chloride, cooling by ether, cocaine, alpin, and the like.<sup>17</sup>

After the provocative injection of the active principles is made intravenously, there is manifest a modified response of the blood vessels of the tissues at sites distant from the local reaction. This is best demonstrated by the application of suction, pulling of hair, shaving with a dull razor, and the like. The normal skin sites thus treated develop petechial hemorrhages which, microscopically, consists of capillary dilatation and extravasation of erythrocytes. The enhanced fra-

gility of the capillaries in sites distant from the local reaction may be demonstrated for a period of from four to forty-eight hours following the provocative injection of bacterial filtrates and depends on the severity of the local lesion (Shwartzman).

The tendency toward the hemorrhagic diathesis described cannot be correlated, as yet, with blood changes. In recent unpublished experiments of Mintz, of these laboratories, no distinct changes were observed in coagulation and bleeding time. It appears, therefore, that the changes observed are to be ascribed primarily to certain modifications in the behavior of the blood capillaries themselves.

It is also possible to demonstrate that other changes take place in sites not directly affected by the local

Fig. 6.—Swine: Hog cholera; many glomeruli with capillary thrombi.

reaction which predispose toward an exaggerated tendency to the formation of thrombi. When the phenomenon is elicited in the rabbit's ear by combined intradermal and intravenous injection of the active principles, sites distant from the local reaction frequently become cyanotic. In such sites it is possible to detect, microscopically, thrombosis of the venules not accompanied by inflammatory perivascular reactions.

Thus, the essential morphologic features of the phenomenon seem to express themselves in combined severe vascular damage, inflammation and necrosis at the sites of highest reactivity with subsequent repercussion of this reaction on the blood vessels distant from it, manifesting itself in altered vascular response with the formation of thrombi. The manifestations therefore offer a basis for the experimental demonstration of conditions of hemorrhagic diathesis, the mechanism of which essentially consists of the following distinct phases:

Elicitation of a latent vascular reactivity followed by the production of local vascular lesions when certain reacting factors are superimposed at suitable times, and an incidental effect of the local lesion on distant capillaries which leads to a tendency to thrombosis and to other expressions of altered vascular response (capillary "toxicosis"); i. e., hemorrhage following mechanical or other injury.

As previously mentioned, while the state of reactivity can be elicited exclusively by certain bacterial principles, potent provocative factors may be obtained not only from bacteria but from combinations of animal proteins with homologous antibodies. Thus, it is possible to fit into the experimental observations presented, at least in the form of a working hypothesis, the two major groups of hemorrhagic diathesis, namely:

Symptomatic purpura of infectious diseases in which bacterial factors alone may be implicated in the production of all the phases, and the so-called anaphylactoid conditions of hemorrhagic diathesis in which there

may be assumed the combined effect of bacterial reactivity with subsequent response to nonrelated anaphylactic processes.

In addition to the foregoing considerations, comparative studies of experimental and spontaneous lesions in animal and man suggest the significance of the phenomenon in the pathogenesis of certain morbid processes. There is a group of cases in which the histologic picture points to the possible rôle of toxins in their etiology because of the predominance of thrombi within the terminal vascular bed and hemorrhagic diathesis, although bacteriologic investigations have failed to demonstrate the etiologic factor. In 1925 Moschkowitz<sup>18</sup> described such a case. Recently Friedberg and Gross,<sup>19</sup> and Baehr, Klemperer and Schiffrin<sup>20</sup> reported cases with identical clinical and anatomic features. The chief clinical changes were thrombocytopenia and purpura with a positive tourniquet test and an acute febrile anemia. Anatomically they were distinguished by widespread thrombosis of the arterioles and capillaries affecting practically every organ, and parenchymatous hemorrhages with striking dilatation of the venules and capillaries. It is noteworthy that these cases occurred in females exclusively, which points to a still unknown additional factor in their pathogenesis.

The rôle of the phenomenon in the production of experimental renal lesions by intravascular preparation has already been mentioned. Morphologic studies manifest a striking similarity with focal or diffuse symmetrical cortical necrosis of the kidneys seen in eclampsia and various infectious conditions (sepsis, scarlet fever, malaria and the like), and in epizootic diseases; i. e., hog cholera and swine erysipelas. Although, as already indicated, renal lesions were obtained only when two injections of bacterial filtrate were given, Apitz<sup>14</sup> succeeded in obtaining the lesions

Fig. 7.—Autopsy study in an infant aged 18 months: Generalized miliary tuberculosis. Glomerulus with granular thrombi within dilated capillaries.

in pregnant animals following the intravenous administration of only a single injection. Similar experiments are under way. Thus far the kidney alterations have been obtained once in ten pregnant animals used.

Apitz considered pregnancy to represent a state of generalized increased reactivity comparable to that obtained experimentally by the introduction of the first dose of bacterial filtrate so that only a single dose was required to elicit the phenomenon. The pathogenesis of bilateral cortical renal necrosis in pregnancy in human beings has similarly been considered by Scriver and Oertel<sup>21</sup> to be related to a general state of abnormal vasomotor irritability.

The occurrence of thrombotic lesions in the arterioles, venules and capillaries in the internal organs in infectious and toxic states in human beings has long been known and has often been referred to as toxic thrombosis. Experiments undertaken by Kusama<sup>22</sup> to explain the nature of these thrombi revealed that, among other things, the injection of bacterial vaccines would elicit such vascular thrombosis in rabbits. Subsequently, Siegmund,<sup>23</sup> who had observed similar thrombi in chronic sepsis in human beings, succeeded in producing these lesions in animals by the repeated injection of bacterial vaccines over a prolonged period of time (*B. coli*, *Streptococcus*, and other microorganisms) followed by live organisms. He considered the thrombi to be the result of endothelial damage due to sensitization by the vaccines and postulated that an identical mechanism was operative in chronic infections in human beings. For many years we have seen similar thrombotic lesions in a variety of infections. Bacteria were not found in the thrombi. It is questionable whether or not such lesions should also be interpreted as the result of an altered vascular response, since Apitz and Gerber were able to produce similar thrombi in the internal organs of rabbits exclusive of the kidneys by the intravenous injection of a single dose of bacterial filtrate. In their attempts to produce the phenomenon of local tissue reactivity in the kidneys by the vascular route, they observed that control animals which had received only a single intravenous injection of bacterial filtrate very frequently showed the presence of thrombi in the veins and capillaries of the lungs, liver, spleen, adrenals and bone marrow. It is very likely that the active factor in the vaccines used by Kusama and Siegmund, responsible for the thrombotic lesions, is identical with the active principles of the phenomenon since the latter are heat resistant and may be present in vaccines.

The similarity of the thrombi produced by the injection of bacterial filtrates with those seen in human beings strongly suggests that the latter are also due to toxins and are therefore to be regarded as manifestations of a toxemia associated with bacterial infections.

#### SUMMARY

1. The phenomenon of local tissue reactivity to bacterial antigenic principles, consisting of a preparatory and provocative injection, which may be elicited in various organs, expresses itself in a vascular damage leading to hemorrhage and thrombosis.

2. This is associated with a modified vascular response to various stimuli at sites distant from the local lesion.

#### ABSTRACT OF DISCUSSION

DR. GREGORY SHWARTZMAN, New York: The question was asked, Does the author believe that his phenomenon is only a particular phase of the Arthus phenomenon or that it is a separate, distinct phenomenon? I would refer the inquirer to numerous publications dealing with the subject, in which the difference is shown very clearly. I am afraid there would not be enough time to take it up now.

#### ROENTGEN KYMOGRAPHY IN DISEASES OF THE HEART

A RELATIVELY NEW AND EFFICIENT AID  
IN DIAGNOSIS

WENDELL G. SCOTT, M.D.  
AND  
SHERWOOD MOORE, M.D.  
ST. LOUIS

A new and useful method has recently been developed for graphically recording the physiologic movements of an organ or structure on a single x-ray film. This procedure is called roentgen kymography. The basic principle was first conceived by the Polish physiologist Sabat<sup>1</sup> in 1911 and independently by Gott and Rosenthal<sup>2</sup> in 1912. Crane,<sup>3</sup> Hitzenger<sup>4</sup> and Knox<sup>5</sup> improved the technic, but it was Pleikart Stumpf<sup>6</sup> of Munich who devised the multiple-slit grid and perfected the apparatus mechanically, so that by 1931<sup>7</sup> the method was practical, inexpensive and of clinical value. I. Seth Hirsch<sup>8</sup> introduced Stumpf's work to American radiologists and made important and original contributions of his own, particularly in synchronizing the recording of the heart sounds, the electrocardiogram and the kymogram.

A clear and thorough understanding of the kymographic method is absolutely necessary in order to interpret the films, or kymograms, as they are called. The essential part of a kymograph is the grid (fig. 1). This is a large sheet of lead in which narrow, horizontal slits are cut every 12 mm. apart. The opening in each slit is 0.4 mm. wide. The patient stands next to the

grid and during a continuous exposure of one and one-fourth seconds the cassette slowly moves down behind the fixed grid a distance slightly less than the space between two slits—actually 11 mm. Thus between every 11 mm. of exposed film there is 1 mm. of white, unexposed film, which divides the kymogram into frames (fig. 2). It must be constantly kept in mind

Fig. 1.—Schema of roentgen kymograph: The patient stands next to the grid and during a continuous x-ray exposure of one and one-fourth seconds the film slowly moves down behind the fixed grid a distance slightly less than the width between two slits—actually 11 mm. Thus there remains 1 mm. of white, unexposed, film, which divides the kymogram into frames (fig. 2). Roentgen kymography records simultaneously the movements of multiple points on the border of the heart. These points are the small areas on the heart border that overlie a slit. Thus the horizontal movements at the heart border produced by the filling and emptying of the heart during diastole and systole are recorded in wave form. Each frame is then a record of the movement of one of these points over 11 mm. of film.

that this method records simultaneously the movements of multiple points on the border of the heart or structure roentgenographed. The points recorded are those small areas on the heart border which overlie a slit in the grid.

By this procedure the horizontal movements at the heart border produced by the filling and emptying of the heart during diastole and systole are recorded in wave form. The vertical component of a movement is registered by placing the grid in the vertical position and moving the film horizontally. Parts that do not move, or move at right angles to the slits, appear as perpendicular straight lines. It is well to emphasize that each frame is a record of the movements of a very small segment on the heart border registered over 11 mm. of film.

#### INTERPRETATION OF KYMOGRAMS

The size and shape of the heart are studied in the same manner as in the usual roentgenogram. The trough of a wave is that particular point at maximum systole and the peak of the wave is the same point at maximum diastole. The lower leg of the wave is a record of the diastolic phase of the cardiac cycle, and the upper leg is a record of the systolic phase.

The speed and amplitude of a movement alter the contour of the resulting waves, and these factors must be appreciated when analyzing kymograms.

The time occurrence of movements in the different cardiac chambers and great vessels is determined by tracing side by side the waves in the various frames on

a sheet of ruled paper. Each tracing is begun at the white line at the bottom of the frames. The time relationship of the movements is then established by drawing parallel lines, and all points on the same parallel line occur at the same instant. For example, it is seen that the straight limbs of the ventricular and aortic waves occur simultaneously but run in opposite directions. The quick ventricular movement is from within outward as the result of its sudden filling by ventricular systole. Since the film moves at a uniform rate of speed, every millimeter which the film travels will correspond to a definite period of time. This makes it possible to calculate the time duration of any movement (fig. 3).

#### CARDIAC KYMOGRAPHY

In cardiology, kymography provides information of two sorts. First: Each chamber produces characteristic waves, and this makes it possible to identify the position and extent of the chambers in the cardiac silhouette. Fetzer's<sup>9</sup> work clearly demonstrates that in the erect position the right lower heart border is formed by the right ventricle (fig. 2). The chambers constituting the posterior cardiac shadow are recognized by making a kymogram while the patient is swallowing an opaque

Fig. 2.—"Step-kymogram" of a normal heart: The size and shape of the heart are studied in the same manner as are the usual chest films. The trough of a wave is a particular point at maximum systole, while the peak of the wave is the same point at maximum diastole. The lower leg of the wave is a record of the diastolic phase of the cardiac cycle, and the upper leg a record of the systolic phase. Over the left heart border in frames 8 to 16 are the characteristic waves of the left ventricle; frames 6 to 7, left auricle; frame 5, pulmonary artery; frames 1 to 3, descending aorta. On the right border in frames 13 to 15 are the waves of the right ventricle; frames 10 to 12, right auricle with the superimposed ventricular waves. Frames 8 and 9 are possibly waves of the right auricular appendage. The points on the ribs and diaphragm that overlie a slit appear as steplike shadows. Structures that do not move or move at right angles to the slits appear as straight vertical lines.

meal. In this way the movements of the different chambers are imparted to the esophagus and can be recorded. The second type of information is derived

9. Fetzer, Hans: Die Lage des rechten Vorhofes und des rechten Ventrikels beim stehenden Menschen, Fortschr. a. d. Geb. d. Röntgenstrahlen 46: 29-36, Kongressheft. 1932.

from a careful study of the movements as recorded in the form of the waves: (a) changes in the movements as a whole and (b) changes in the individual waves.

(a) The most striking example of alteration in the movement of the whole heart is seen in the case of constrictive adhesive pericarditis, as has been described by Johnson.<sup>10</sup> In this case and in the case of tuberculous pericarditis reported by us<sup>11</sup> there was practically complete absence of motion over the left ventricle and right auricle, as evidenced by the straight, vertical lines on the kymograms. The aortic waves were greatly diminished. Ihre's<sup>12</sup> experience was similar with a case in which the pericardium was thickened. Stumpf<sup>7</sup> reported that in pericardial effusion the movement waves are very small.

A region of pleuropericardial-diaphragmatic adhesions<sup>13</sup> is shown as a localized area devoid of all motion in the presence of adequate cardiac motion elsewhere.

A zone of cardiac infarction<sup>14</sup> is recognized by the absence of motion in several frames with ample motion in the adjacent frames (fig. 4).

The kymogram gives a clear picture of myocardial tonicity. Ventricular waves of small amplitude with little superimposed irregularities and notches are indicative of a weakened and damaged myocardium. These

Fig. 3.—Method of determining the time relationship of movements in the different cardiac chambers and great vessels: The waves in the various frames are traced side by side on a sheet of ruled paper. The tracings are begun on the white line at the bottom of the frames. The time relationship of the movements is then established by drawing parallel lines, and all points on the same parallel line occur at the same instant. a, point at which first heart sound occurs; b, notch corresponding to second heart sound. (Hirsch.)
